

Fig. 56.

We may pursue the subject much farther, by combining particular solutions like those given but taken from different origins. We can afford space for one only. Let  $P, Q$  (fig. 57) be points on the axis of  $x$ , distant  $a$  and  $-a$  from the origin,  $R$  any point in the plane of the figure. Let  $PR=r$ ,  $\angle RPQ=\theta$ ,  $RQ=r_1$ ,  $\angle RQP=\theta_1$ . Then if

$$A = \log r - \log r_1, \\ A' = \theta - \theta_1,$$

we must have, not only the equation

$$\frac{\partial^2 A}{\partial x^2} + \frac{\partial^2 A}{\partial y^2} = 0$$

satisfied by each of  $A$  and  $A'$ , but also the conditions

$$\frac{\partial A}{\partial x} = \frac{\partial A'}{\partial y}, \quad \frac{\partial A}{\partial y} = -\frac{\partial A'}{\partial x}.$$

This follows at once from the fact that all the equations are linear.

§ 214. In fig. 57 we have  $\epsilon^A = PR/QR$ . Hence the locus of  $R$  is a circle, whose centre,  $B$ , is on  $QP$  produced.

Again  $A' = \angle RPQ - \angle RQP = \angle PRQ$ . The locus of  $R$  is, in this case, any circle passing through  $P$  and  $Q$ .

These circles evidently cut one another orthogonally in  $R$ ; for  $BR$ , which is a radius of the one, is a tangent to the other.

Thus particles moving in a plane, so that the speed at any point  $R$  is inversely as  $PR \cdot RQ$ , may describe circles in which  $PQ$  is a chord. In this case the curves of equal action are circles defined by the condition that the ratio  $PR : RQ$  is constant. Or they may move in the latter system of circles, in which case the former system gives the lines of equal action. For the equations in the preceding section give

$$v^2 = \left(\frac{\partial A}{\partial x}\right)^2 + \left(\frac{\partial A}{\partial y}\right)^2 = \left(\frac{\partial A'}{\partial x}\right)^2 + \left(\frac{\partial A'}{\partial y}\right)^2 = \frac{4a^2}{r^2 r_1^2};$$

from which the conclusion is obvious.

We may easily extend this example to other sets of orthogonal curves whose equations are

$$A_1 = pA + A', \\ A'_1 = -A + pA',$$

where  $A$  and  $A'$  have their recent values. Or we may extend the example by assuming at starting

$$A = m \log r - m_1 \log r_1,$$

in which case it will be found that we must have

$$A' = m\theta - m_1\theta_1.$$

These pairs may again be combined into

$$pA + A' \text{ and } -A + pA', \text{ and so on.}$$

Fig. 57.

It will be noticed that in these examples the curves of equal action and the paths of the particles correspond in steady fluid motion between to curves of equal pressure and lines of flow, and in electric conduction to equipotential lines and current lines. In such cases in fact, where there is no vortex-motion, the action is closely analogous to what is called the "velocity potential" in a fluid.

### Generalized Coordinates.

§ 215. By the help of the result already obtained in connexion with least action, we may easily obtain in a simple, though indirect, way the remarkable transformation of the equations of motion of a system which was first given by Lagrange. We are not prepared to give here the transformation to *Generalized Coordinates* in its most general form; but, even in the restricted form to which we proceed, it is almost invaluable in the treatment of the motion of conservative systems of particles in which the number of degrees of freedom is less than three times that of the particles. The one point to be noticed is that, when we restrict ourselves to a system of this kind, the expression for the kinetic energy,  $T$ , is necessarily a pure quadratic function of the rates of increase of the generalized coordinates. This is obvious from § 19. Repeating with generalized coordinates the investigation of § 202, we have

$$A = 2 \int T dt = \int (T + H - V) dt.$$

Hence

$$\delta A = \int (\delta T + \delta H - \delta V) dt.$$

Now let  $\theta, \phi, \psi$ , &c., be the generalized coordinates, and we have

$$2T = P\dot{\theta}^2 + 2Q\dot{\theta}\dot{\phi} + R\dot{\phi}^2 + \dots$$

where  $P, Q, R, \dots$  are in general functions of  $\theta, \phi, \psi, \dots$ . Of course  $V$  is a function of  $\theta, \phi, \psi, \dots$  alone, and does not involve  $\dot{\theta}, \dot{\phi}, \dot{\psi}$ , &c.

Thus we have, writing for one only of the generalized coordinates,

$$\delta A = \int \left( \left( \frac{\partial T}{\partial \dot{\theta}} \right) \delta \dot{\theta} + \left( \frac{\partial T}{\partial \dot{\phi}} \right) \delta \dot{\phi} - \left( \frac{\partial V}{\partial \theta} \right) \delta \theta \right) dt + \int \delta H dt \\ = \int \left( \frac{\partial T}{\partial \dot{\theta}} \delta \dot{\theta} \right) dt + \int \delta H dt - \int dt \left[ \left( \frac{d}{dt} \left( \frac{\partial T}{\partial \dot{\theta}} \right) - \frac{\partial T}{\partial \theta} + \frac{\partial V}{\partial \theta} \right) \delta \theta \right].$$

But we saw that, for any natural motion, the unintegrated part of  $\delta A$  necessarily vanishes. Thus, as  $\theta, \phi, \psi, \dots$ , and, therefore, their variations, are by their very nature independent of one another, the vanishing of the unintegrated part gives us one equation of motion for each degree of freedom, the type being in all of them the same, viz.,

$$\frac{d}{dt} \left( \frac{\partial T}{\partial \dot{\theta}} \right) - \left( \frac{\partial T}{\partial \theta} \right) + \left( \frac{\partial V}{\partial \theta} \right) = 0.$$

To exemplify the use of these equations we will take again a few Examples of the more important cases of constraint already treated, and will then proceed to some others of interest as well as of somewhat greater complexity.

In the simple pendulum,  $l$  being again the length of the string, and  $\theta$  the inclination to the vertical at time  $t$ , we have obviously

$$T = \frac{1}{2} m l^2 \dot{\theta}^2, \quad V = C - mgl \cos \theta.$$

$$\text{Hence} \quad \left( \frac{\partial T}{\partial \dot{\theta}} \right) = m l^2 \dot{\theta}, \quad \left( \frac{\partial T}{\partial \theta} \right) = 0, \quad \left( \frac{\partial V}{\partial \theta} \right) = mgl \sin \theta.$$

Thus the equation of motion is

$$m l^2 \ddot{\theta} + mgl \sin \theta = 0$$

or

$$\ddot{\theta} + \frac{g}{l} \sin \theta = 0,$$

as in § 134.

Suppose the same pendulum to be moving anyhow,  $\theta$  still denoting its inclination to the vertical, and  $\phi$  denoting the azimuth of the plane in which it is displaced, we have

$$T = \frac{1}{2} m l^2 (\dot{\theta}^2 + \sin^2 \theta \dot{\phi}^2), \quad V = C - mgl \cos \theta$$

These give at once

$$\left( \frac{\partial T}{\partial \dot{\theta}} \right) = m l^2 \dot{\theta}, \quad \left( \frac{\partial T}{\partial \dot{\phi}} \right) = m l^2 \sin \theta \cos \theta \dot{\phi}, \quad \left( \frac{\partial V}{\partial \theta} \right) = mgl \sin \theta, \\ \left( \frac{\partial T}{\partial \phi} \right) = m l^2 \sin^2 \theta \dot{\phi}, \quad \left( \frac{\partial T}{\partial \phi} \right) = 0, \quad \left( \frac{\partial V}{\partial \phi} \right) = 0.$$

Hence the two equations are

$$\ddot{\theta} - \sin \theta \cos \theta \dot{\phi}^2 + \frac{g}{l} \sin \theta = 0,$$

$$\frac{d}{dt} (\sin^2 \theta \dot{\phi}) = 0.$$

Pendulum with extensible cord. Still keeping to easy examples, suppose the cord of the ordinary simple pendulum to be extensible, according to Hooke's law. Let  $\lambda$  be its length at time  $t$ . Then the tension is  $E(\lambda - l)/l$ , and the work it can do in contracting is the integral of this with regard to  $\lambda$  from  $l$  to  $\lambda$ , i.e.,

$$E(\lambda - l)^2/2l.$$

Hence we have  $V = C + E(\lambda - l)^2/2l - mg\lambda \cos \theta$ ,

$$T = \frac{1}{2}m(\lambda^2\dot{\theta}^2 + \dot{\lambda}^2).$$

Thus Lagrange's equations become

$$\frac{d}{dt}(\lambda^2\dot{\theta}) + g\lambda \sin \theta = 0,$$

$$m\ddot{\lambda} - m\lambda\dot{\theta}^2 + E(\lambda - l)/l - mg \cos \theta = 0;$$

equations which could be obtained immediately from the application of the second law, with the help of the kinematical expressions for acceleration perpendicular to, and along, the radius-vector of a plane curve (§ 47).

Instead of the complex pendulum treated in § 177, we will now take the case of two masses attached at different points to an elastic string, or light helical spring, and consider their vertical vibrations.

Let  $a, b$  be the unstretched lengths of the parts of the string,  $M$  and  $m$  the masses. Then if  $\xi, \eta$  be the vertical displacements at time  $t$ , we have

$$T = \frac{1}{2}(M\dot{\xi}^2 + m(\dot{\xi} + \dot{\eta})^2),$$

$$V = \frac{E}{2}\left(\frac{\xi^2}{a} + \frac{\eta^2}{b}\right) - Mg\xi - mg(\xi + \eta);$$

so that Lagrange's equations are

$$\frac{d}{dt}(M\dot{\xi} + m(\dot{\xi} + \dot{\eta})) + E\frac{\xi}{a} - (M + m)g = 0,$$

$$\frac{d}{dt}(m(\dot{\xi} + \dot{\eta})) + E\frac{\eta}{b} - mg = 0.$$

The equilibrium positions are found by supposing the accelerations to vanish, so that, if we suppose  $\xi$  and  $\eta$  to be measured from them, the terms in  $g$  will disappear. Hence the solution is of exactly the same nature as that already given for an apparently different problem (§ 178).

We may mention that equations practically the same as these are obtained when we consider the motions of a watch and its balance-wheel, the watch being supported in a horizontal position by means of a wire, and oscillating in its own plane by the torsion-elasticity of the wire. The reader of § 242 below will have no difficulty in obtaining this result. It suggests a practical method of "setting" a watch to true time, without turning the hands forward or backward, and without letting it run down.

The following is a simple, but very instructive, example of the transference of energy (back and forward) between two parts of a system. Two bar-magnets of equal mass, length, and strength (fig. 58), are supported horizontally by pairs of parallel strings, so that when at rest they are in one line. One of them is slightly displaced in the direction of its length, find the subsequent motion of both.<sup>1</sup>

If we can, by any process, find two fundamental states of motion which, once established, will be permanent, any other possible motion of the system will be a superposition of these two. The amplitudes and phases in the components may have any values, so long as the whole disturbance is small. This follows from the fact that the system has two degrees of freedom only,—since we are concerned only with motions in the plane of the figure.

(A) Now one obviously possible motion is a simple harmonic vibration of the whole, without change of distance between the magnets. The period of this vibration is obviously the same as that of either magnet if the other were removed.

(B) Another obviously possible motion is that in which the magnets are, at every instant, equally and oppositely

Fig. 58.

<sup>1</sup> We suppose the bars to be so long, in comparison with the distance between them, that we need take account only of the action of their poles which are turned towards one another.

deflected. The period of this oscillation will be less or greater than that of the former according as the poles attract or repel one another.

Now the initial state of motion proposed evidently consists of the superposition of (A) and (B) in such a way that there is, at starting, no displacement of either mass, but a definite velocity of one of them only. This corresponds to simultaneous zero of displacement, with equal velocities, for each of (A) and (B). There is therefore at that instant no displacement of either mass; and one is at rest while the other is moving with double the assigned velocity. If  $2\pi/n, 2\pi/n'$  be the periods of the two motions, it is obvious that after the time  $\pi/(n - n')$  the magnets will have interchanged their states so that the arrangement will present exactly the same appearance as at first, *if looked at from the other side*.

Let  $a$  be the distance between the ends of the bars when all four strings are vertical. Then, if  $\theta, \phi$  be at time  $t$  the inclinations of the pairs of strings to the vertical,  $a$  becomes

$$D = a + l(\phi - \theta),$$

where  $l$  is the common length of the strings. The expression for the potential energy due to magnetism is of the form  $\mu/D$ , where  $\mu$  is positive if like poles be turned to one another.

Hence

$$T = \frac{1}{2}m\dot{\theta}^2 + \frac{1}{2}m\dot{\phi}^2,$$

$$V = \frac{1}{2}mg\dot{\theta}^2 + \frac{1}{2}mg\dot{\phi}^2 + \frac{\mu}{a + l(\phi - \theta)}.$$

Forming the equations as usual, and omitting powers of  $\theta$  and  $\phi$  above the first, we have

$$m\ddot{\theta} = -mg\theta + \frac{\mu l}{a^2}\left(1 - \frac{2l}{a}(\phi - \theta)\right),$$

$$m\ddot{\phi} = -mg\phi - \frac{\mu l}{a^2}\left(1 - \frac{2l}{a}(\phi - \theta)\right);$$

from which the results already given may be deduced.

Finally, let us take the case of Atwood's machine (§ 173) when Atwood's the masses are equal, and one of them is vibrating through small machine arcs.

Let  $r, \theta$  be the polar coordinates of the vibrating mass; then, One mass neglecting powers of  $\theta$  higher than the second, we have the general- vibrating ized equations

$$2r - r\dot{\theta}^2 = -\frac{1}{2}g\theta^2,$$

$$\frac{d}{dt}(r^2\dot{\theta}) = -gr\theta.$$

Put  $\frac{1}{2}gr$  for  $r$ , and  $\theta/\sqrt{2}$  for  $\theta$ , and we get

$$\ddot{r} - r\dot{\theta}^2 = -\theta^2,$$

$$\frac{1}{r}\frac{d}{dt}(r^2\dot{\theta}) = -2\theta.$$

Transform to rectangular coordinates in the plane of motion,  $x$  being vertically downwards; then

$$\ddot{x} = y^2/x^2, \quad \ddot{y} = -2y/x.$$

This shows that the vertical acceleration of the vibrating particle is very small, but constantly downward. Hence the energy of the vibratory motion is steadily converted into energy of translation of the masses.

When both the equal masses vibrate through small arcs, it is found that the mass whose angular range is the greater has downward acceleration with diminishing angular range. Hence it would appear that, if the string be long enough, the entire motion would be periodic.

§ 216. Before leaving this subject we may form, from the complete value of  $\delta A$  given in last section, the generalized equations corresponding to those of Hamilton's "varying action," as given in § 204.

We have at once

$$\left(\frac{\delta A}{\delta \theta}\right) = \left(\frac{\delta T}{\delta \dot{\theta}}\right), \left(\frac{\delta A}{\delta \phi}\right) = \left(\frac{\delta T}{\delta \dot{\phi}}\right), \dots, \left(\frac{\delta A}{\delta H}\right) = -t.$$

But, by the value of  $T$ , we have

$$\left(\frac{\delta T}{\delta \dot{\theta}}\right) = P\dot{\theta} + Q\dot{\phi} + \dots$$

$$\left(\frac{\delta T}{\delta \dot{\phi}}\right) = Q\dot{\theta} + R\dot{\phi} + \dots$$

&c. — &c.

These equations give  $\theta, \phi, \dots$  as homogeneous linear functions of  $\left(\frac{\partial T}{\partial \theta}\right), \left(\frac{\partial T}{\partial \phi}\right), \dots$  that is, of  $\left(\frac{\partial A}{\partial \theta}\right), \left(\frac{\partial A}{\partial \phi}\right), \dots$ . Thus, if we substitute these expressions in the equation

$$2T = \sum \left[ \theta \left( \frac{\partial T}{\partial \theta} \right) \right] = \sum \left[ \theta \left( \frac{\partial A}{\partial \theta} \right) \right],$$

which is obviously true, because  $T$  is a homogeneous function of  $\theta, \phi, \dots$  of the second degree, we have a partial differential equation of the form

$$p \left( \frac{\partial A}{\partial \theta} \right)^2 + 2q \left( \frac{\partial A}{\partial \theta} \right) \left( \frac{\partial A}{\partial \phi} \right) + r \left( \frac{\partial A}{\partial \phi} \right)^2 + \dots = 2(H - V),$$

from which  $A$  is to be found.

The coefficients  $p, q, r, \dots$  are, in general, like  $P, Q, R, \dots$  functions of  $\theta, \phi, \dots$ .

As an illustration, take again the example in last section, where two masses are attached to a helical spring, and vibrate in a vertical line. From the value of  $T$  there given we have

$$\begin{aligned} \left( \frac{\partial A}{\partial \xi} \right) &= \left( \frac{\partial T}{\partial \xi} \right) = (M + m)\dot{\xi} + m\dot{\eta}, \\ \left( \frac{\partial A}{\partial \eta} \right) &= \left( \frac{\partial T}{\partial \eta} \right) = m\dot{\xi} + m\dot{\eta}. \end{aligned}$$

From these we have the equation for  $A$

$$m \left( \frac{\partial A}{\partial \xi} \right)^2 - 2m \left( \frac{\partial A}{\partial \xi} \right) \left( \frac{\partial A}{\partial \eta} \right) + (M + m) \left( \frac{\partial A}{\partial \eta} \right)^2 = 2Mm(H - V).$$

The value of  $V$  is given above. This equation is, of course, to be treated according to the process illustrated in § 209.

#### STATICS OF A RIGID SOLID.

§ 217. A rigid body, as we have already seen, has at the utmost six degrees of freedom, three of translation and three of rotation. According to Newton's scholium, the conditions of equilibrium of such a body, under the action of any system of forces, are that the algebraic sum of the rates of doing work by and against the forces shall be *nil* whatever uniform velocity of translation or of rotation the body may have. For, if this were not so, there would be work done against acceleration, and the body would gain or lose kinetic energy. And this gain or loss would take place even if the body were originally at rest, *i.e.*, it would not be in equilibrium. To ensure equilibrium then, all that is necessary is that the sums of the components of the forces in any three non-coplanar directions shall vanish, along with the sums of their moments about any three non-coplanar lines. For simplicity it is usual to assume for these directions a system of rectangular axes, and for the lines another system parallel to them and passing through some definite point (say the centre of inertia) of the body.

Thus we have at once

$$\begin{aligned} \sum(X) &= 0, \quad \sum(Y) = 0, \quad \sum(Z) = 0; \\ \sum(Zy - Yz) &= 0, \quad \sum(Xz - Zx) = 0, \quad \sum(Yx - Xy) = 0, \end{aligned}$$

where  $X, Y, Z$  are the components, parallel to the axes, of a force acting at the point  $x, y, z$  of the body. If  $P$ , with direction cosines  $\lambda, \mu, \nu$ , represent the force acting at  $x, y, z$ , these equations may be written in the form

$$\begin{aligned} \sum(P\lambda) &= 0, \quad \sum(P\mu) = 0, \quad \sum(P\nu) = 0 \\ \sum\{P(\nu y - \mu z)\} &= 0, \quad \sum\{P(\lambda z - \nu x)\} = 0, \quad \sum\{P(\mu x - \lambda y)\} = 0 \end{aligned}$$

These equations correspond to the six degrees of freedom involved.

It is easy to see that it is a mere matter of convenience through what point of the body we draw the lines about which moments are taken. For, if we shift it by quantities  $a, b, c$  respectively, the moments become

$$\sum\{Z(y-b) - Y(z-c)\}, \text{ \&c. ;}$$

but these are  $\sum(Zy - Yz) - b\sum(Z) + c\sum(Y)$ , \&c. ;

and, by the first three equations, these quantities are seen to reduce themselves to their first terms. Hence, in forming the equations of equilibrium, simplicity will be gained by choosing as origin a point through which the line of action of one or more of the applied forces passes.

Again, the point of application of any one of the forces may be

shifted at will anywhere along the line in which the force acts. For the equations of the line in which the force at  $x, y, z$  acts are

$$\frac{x-x'}{X} = \frac{y-y'}{Y} = \frac{z-z'}{Z},$$

and these give

$$Zy' - Yz' = Zy - Yz, \text{ \&c. ,}$$

so that the expressions for the moments are unaltered if the point of application of the force be shifted to any position along the line in which it acts.

§ 218. In the great majority of treatises on Statics the fundamental propositions of the subject, above given, are deduced from the assumption (as a thing to be proved experimentally) of the result just established, which is designated the "principle of the transmission of force." Along with it are assumed the parallelogram of forces, and the principle of the "superposition of systems of forces in equilibrium." Since the publication of the *Principia*, the continued use of such methods must be looked upon as a retrograde step in science.

§ 219. From this category we cannot quite except (so far as Couple at least as the usual modes of treating it are concerned) the valuable idea of the "couple," due to Poinso. But the term is in such common use, and the idea in its applications sometimes of such importance, that it cannot be omitted here.

*A couple is a pair of equal forces acting on the same body in opposite directions and in parallel lines.*

From the general conditions already given we see that a couple produces a definite moment of force about a particular axis, but that the axis is determinate merely as regards direction, and not as regards position in space. The forces of a couple do not appear in the first three of the equations of equilibrium. On the other hand, the left hand members of the other three equations may all be regarded as moments of couples. All the properties of couples are contained in these statements. Thus, for instance, it is obvious that, so far as its effects are concerned—

1. A couple may be shifted by translation to any other position in its own plane. Transference of couple.
2. It may be shifted to any parallel plane.
3. In either of these it may be turned through any angle.
4. Its forces may be increased or diminished in any ratio, provided the distance between their lines of action (which is called the "arm" of the couple) be proportionately diminished or increased. Arm of couple.

A couple is therefore completely determined by means of its "axis," which is a line drawn perpendicular to its plane, and of length representing its moment. And two couples are obviously to be compounded by treating their axes as if they were forces acting at one point.

§ 220. We will now examine the consequences of the six conditions of equilibrium (§ 217) in some of the more common cases which present themselves. But, before doing so, it may make matters clearer if we restate these conditions in a somewhat different form. Reduction of a system to a force and a couple.

*The resultant of any number of forces, acting at any points of a rigid body, may be represented by a single force acting at the origin, and a couple of definite moment about a definite line passing through the origin.*

*For equilibrium of the body this force and couple must separately vanish.*

Thus if, in fig. 59,  $P$ , acting at  $Q$ , be any one of the forces, and  $O$  the origin (chosen at random), we may introduce at  $O$  a pair of equal and opposite forces  $\pm P$ , parallel to  $P$ . The original force, taken along with  $-P$  at the origin, gives a couple; and in addition there is  $+P$  acting at the origin.

Fig. 59.

§ 221. When only two forces act on a body, the first

condition above shows that they must be equal and opposite, and the second that they must act in the same line, if they are to maintain equilibrium. When only three forces act, the first condition shows that their directions must lie in one plane, the second that their lines of action must be parallel or must meet in one point, if they are to maintain equilibrium.

If their directions meet in one point we have again the problem of the equilibrium of a single particle under three forces; for there can be no moment about this point.

When the directions are parallel, one of the forces must obviously be equal to the sum of the other two, and must act in the opposite direction. Also its line of action must lie between those of the other two, for their moments about any point in it must be equal and opposite. Hence it is impossible that any single force should balance a couple, unless we adopt the mathematical fiction of an infinitely small force acting in a line everywhere at an infinite distance; so that its moment may be finite, and equal and opposite to that of the couple.

Parallel forces. § 222. When any number of parallel forces act simultaneously on a rigid body, their resultant is a single force equal to their algebraic sum, with a couple whose plane is obviously parallel to the common direction of the forces. The forces of this couple may be made, by lengthening or shortening the arm, equal to the resultant force. One of them will neutralize it, and the other remains the final resultant, which passes through a definite point called the "centre of parallel forces." Thus any set of parallel forces necessarily has a single force as a resultant, excepting in the special case when their algebraic sum is zero.

Gravity. § 223. Excellent examples are furnished by heavy bodies of moderate dimensions, where the weights of their parts are forces practically in parallel lines. The single resultant force, in such cases, is the whole weight of the body. Its direction always passes through the centre of inertia (§ 109) because weight (in any one locality) is proportional to mass. For this reason all heavy bodies of moderate dimensions are said to have a "centre of gravity," which coincides with the centre of inertia. But it must be noticed that the two ideas are radically different, and that, while every piece of matter has a true centre of inertia, it is, in general, only approximately that we can predicate of it that it has a centre of gravity. In fact a body has a true centre of gravity only when it attracts, and is attracted by, all other gravitating matter as if its whole mass were concentrated in that point. See POTENTIAL. When there is a centre of gravity in a body, it is necessarily coincident with the centre of inertia. In gravitation cases, where bodies of moderate size are concerned, the resultant is, at least approximately, a single force. But, when we deal with large non-barycentric bodies like the earth, we find that the resultant of the sun's attraction is a force (determining the orbit) and a couple (producing precession, &c.).

When a mass is laid on a three-legged table, we find the pressure which each leg supports by simply taking moments about the line joining the leg joining the upper ends of the other two. The leg is thus seen to support a fraction of the weight of the mass, whose numerator is the distance of the centre of gravity of the mass from this line, and its denominator the distance of the leg from the same line. Thus we have a physical proof of the geometrical proposition that if any point, P, be taken in the plane of a triangle ABC (fig. 60), and perpendiculars be drawn from it and from the angles, we have

$$\frac{P\alpha}{Aa} + \frac{P\beta}{Bb} + \frac{P\gamma}{Cc} = 1.$$

Fig. 60.

If the mass of the table is to be reckoned, P must be taken as the centre of gravity of the system of table and load together. If the table be of uniform material, triangular, and supported by legs at its corners, similar reasoning shows that when it is unloaded (or loaded at its centre of gravity) each leg supports one third of the weight.

§ 224. Examples in which the resultant is a single couple are found in rigidly magnetized bodies placed in a uniform magnetic field. As the amounts of N. and S. magnetism in a body are always equal, there is no force of translation in a uniform field. The resultant couple depends for its magnitude on the orientation of the body, and the positions of equilibrium are those for which its moment vanishes.

§ 225. Let P at  $x, y, z$ , be one of a system of parallel forces, their direction cosines being  $\lambda, \mu, \nu$ . Let Q be the resultant force, and R, with direction cosines  $\lambda', \mu', \nu'$ , the axis of the resultant couple. Then our conditions become

$$Q = \Sigma(P),$$

$$\lambda'R = \Sigma[P(\nu y - \mu z)], \quad \mu'R = \Sigma[P(\lambda z - \nu x)], \quad \nu'R = \Sigma[P(\mu x - \lambda y)].$$

The last three equations give the following conditions determining R,  $\lambda', \mu', \nu'$ :-

$$\begin{aligned} \lambda'R + \mu\Sigma(Pz) - \nu\Sigma(Py) &= 0, \\ -\lambda\Sigma(Pz) + \mu'R + \nu\Sigma(Px) &= 0, \\ +\lambda\Sigma(Py) - \mu\Sigma(Px) + \nu'R &= 0. \end{aligned}$$

From these we have the equation of condition

$$\lambda\lambda' + \mu\mu' + \nu\nu' = 0,$$

showing that the axis of the couple is at right angles to the common direction of the parallel forces.

We have also

$$R^2 = (\Sigma(Px))^2 + (\Sigma(Py))^2 + (\Sigma(Pz))^2 - (\lambda\Sigma(Px) + \mu\Sigma(Py) + \nu\Sigma(Pz))^2.$$

This expression is of the same form as that in § 77, and we therefore conclude that, if  $\lambda'', \mu'', \nu''$  be the direction cosines of a line in the body such that

$$\frac{\lambda''}{\Sigma(Px)} = \frac{\mu''}{\Sigma(Py)} = \frac{\nu''}{\Sigma(Pz)},$$

the magnitude of the resultant couple is directly as the sine of the angle between this line and the common direction of the parallel forces. In fact the mere form of the three equations above proves this result.

In the case of a body of moderate dimensions, acted on by gravity, P is the weight of the element at  $x, y, z$ , and therefore proportional to its mass, so that if the centre of inertia be taken as the origin we have

$$\Sigma(Px) = 0, \quad \Sigma(Py) = 0, \quad \Sigma(Pz) = 0,$$

and there is no couple. The whole effect is therefore the same as if the mass were condensed at the centre of inertia.

In the case of a magnet,

$$\Sigma(P) = 0,$$

and there is no translatory force. The couple, as we have seen, depends upon the orientation of the body as regards the direction of the line of the earth's magnetic force.

§ 226. We have seen that any system of forces acting on a rigid body may be reduced to a force and a couple; also to two forces. that when the force is in the plane of the couple the resultant can always be put in the form of a single force acting in a definite line in the body. When the force is not in the plane of the couple, we may resolve the couple into two components, the plane of one being parallel, of the other perpendicular, to the force. The first, when compounded with the force, merely shifts the line in which it acts. Thus any system of forces may be reduced to a single force, acting in a definite line called the "central axis," and a couple in a plane perpendicular to it. One of the forces of the couple may now be compounded with the single force, and thus we obtain, as the resultant of any system of forces, a pair of forces in non-intersecting lines not perpendicular to one another. This is only one of an infinite number of ways in which fancy, or convenience, may lead us to represent the equivalent of a group of forces. Many very curious theorems have been met with in investigations on this subject. For instance, by compounding one of the forces of the resultant couple with the resultant force (not

now necessarily perpendicular to its plane) we have a system of two forces acting in non-intersecting lines. Then we have the following curious proposition, which may easily be proved from the formulæ already given:—

*When a system of forces is reduced in any manner whatever to two, the volume of the tetrahedron of which these are opposite edges is constant.*

**Symmetrical reduction.** § 227. The most symmetrical pair of resultant forces is found thus. Take any point P (fig. 61) in the central axis, and draw through it a line APA', perpendicular to it, and bisected at P. Substitute for the single force at P its halves acting at A and A' respectively. Combine these respectively with the forces AQ, A'Q' of the couple when AA' is made its arm. The system is thus reduced to two equal forces AR, A'R', whose directions are interchangeable by a rotation of two right angles about the central axis.

Fig. 61.

**General reduction.** Let P with direction cosines  $\lambda, \mu, \nu$  be one of the forces, and let  $x, y, z$  be its point of application. Then

$$X = \Sigma(P\lambda), \quad Y = \Sigma(P\mu), \quad Z = \Sigma(P\nu)$$

are the components of the single force at the origin.

Also

$$L = \Sigma[P(\nu y - \mu z)]$$

$$M = \Sigma[P(\lambda z - \nu x)]$$

$$N = \Sigma[P(\mu x - \lambda y)]$$

are the components of the resultant couple.

If we shift the origin to the point  $a, b, c$  the first three quantities are unaltered, but the couples become

$$L' = L + cY - bZ$$

$$M' = M + aZ - cX$$

$$N' = N + bX - aY.$$

The point  $a, b, c$  is on the central axis if the axis of the resultant couple be parallel to the single force, i.e., if

$$\frac{L'}{X} = \frac{M'}{Y} = \frac{N'}{Z} = e, \text{ suppose;}$$

or

$$L = eX - cY + bZ,$$

$$M = cX + eY - aZ,$$

$$N = -bX + aY + eZ.$$

Either of these sets gives the equations of the central axis.

The resultant force and couple are in one plane, and therefore the resultant is a single force in the central axis, when

$$L'X + M'Y + N'Z = 0.$$

By the values of  $L', M', N'$ , above, we see that this is equivalent

$$LX + MY + NZ = 0.$$

When this last condition is not satisfied, we see that the value of the left hand member which, from the way in which it occurs, must obviously be an invariant, is

$$e(X^2 + Y^2 + Z^2),$$

where  $e$  has the same value as in the three equations above.

**Minding's theorem.**

§ 228. One of the most remarkable of the many curious theorems connected with the single resultant of a system of forces is that of Minding. We have seen that, in general, the resultant may be put in the form of a single force and a couple in a plane perpendicular to it. If we now suppose the system of forces to be shifted into a new position such that their points of application, their magnitudes, and the angles between their directions two and two, all remain unchanged, the resultant force will be of the same magnitude as before, but the couple will in general be different. Of the infinitely infinite number of possible positions which the forces may assume, an infinite number correspond to a zero couple. Minding has shown that the lines of action of these single resultants consist of all lines passing through each of two curves, fixed in the body, an ellipse and an hyperbola, in planes perpendicular to each other. The proof of the proposition gives an interesting example of the use of Rodrigues's coordinates (§ 83).

The most obvious mode of attacking this question would be to resolve the applied forces into three groups, parallel respectively to three rectangular axes which revolve with them, and to choose those axes so that the sum of the resolved parts does not vanish parallel to any one of the three. Each of these systems of parallel forces has its own "centre" (§ 222),—so that the final resolution gives three forces, each of a given magnitude, acting in any mutually perpendicular directions at three definite points in the body. This, however, is not analytically so simple as the following.

We refer the body to fixed axes  $Ox, Oy, Oz$ , to be afterwards specified. As the origin and the directions of these axes are at our disposal, we may impose six conditions. Now suppose the forces to be resolved parallel to a set of rectangular axes  $Ox', Oy', Oz'$  which will be considered afterwards to rotate with them. Such a system of axes may, at starting, have any assigned position. This gives us three conditions more. Let then  $A, B, C$  be the components, parallel to the second set of axes, of the force applied at the point whose coordinates referred to the first system are  $a, b, c$ . Let the direction cosines of the second system in any of its future positions, referred to the first system, be  $l_1, m_1, n_1; l_2, m_2, n_2; l_3, m_3, n_3$  respectively.

Then the force at  $a, b, c$  has the following components:—

$$Al_1 + Bl_2 + Cl_3, \text{ parallel to } Oz'$$

$$Am_1 + Bm_2 + Cm_3, \text{ " " } Oy'$$

$$An_1 + Bn_2 + Cn_3, \text{ " " } Oz$$

The expressions for the resultant force and couple at the origin will evidently depend upon the following twelve quantities, besides the direction cosines, viz:—

$$\Sigma A, \Sigma B, \Sigma C,$$

$$\Sigma(Aa), \Sigma(Ab), \Sigma(Ac),$$

$$\Sigma(Ba), \Sigma(Bb), \Sigma(Bc),$$

$$\Sigma(Ca), \Sigma(Cb), \Sigma(Cc).$$

Assume  $\Sigma B = 0, \Sigma C = 0$ , i.e., let  $Oz'$  be always parallel to the direction of the resultant force. Next, let

$$\Sigma(Aa) = 0, \Sigma(Ab) = 0, \Sigma(Ac) = 0,$$

i.e., let the origin be chosen as the "centre" (§ 222) of the forces parallel to the resultant force. As we have still four conditions to impose, we select the following:—

$$\Sigma(Ba) = 0, \Sigma(Bc) = 0, \Sigma(Ca) = 0, \Sigma(Cb) = 0.$$

These express that the plane of the couple due to the forces  $C$  passes through  $Oy$ , while that of the forces  $B$  passes through  $Oz$ .

Write now

$$\Sigma(A) = \mathfrak{A}, \Sigma(B) = \mathfrak{B}, \Sigma(C) = \mathfrak{C}.$$

The force and couple at the origin are

$$\mathfrak{A}l_1, \mathfrak{B}m_1, \mathfrak{C}n_1,$$

$$\mathfrak{A}(n_2\beta - m_3\gamma), \mathfrak{B}l_2\gamma, -\mathfrak{B}l_2\beta.$$

These are equivalent to a single force if (§ 227)

$$(l_1n_2 - n_1l_2)\beta - (l_1m_3 - m_1l_3)\gamma = 0,$$

or

$$m_2\beta - n_2\gamma = 0 \quad \dots \dots \dots (1)$$

This is the required condition. When it is satisfied, the equations of the line in which the single force  $\mathfrak{A}$  acts are any two of

$$\left. \begin{aligned} n_1\eta - m_1\xi &= n_2\beta - m_3\gamma, \\ l_1\xi - n_1\zeta &= l_2\gamma, \\ m_1\xi - l_1\eta &= -l_2\beta \end{aligned} \right\} \dots \dots \dots (2),$$

the condition that these three agree being (1).

Eliminate  $l_1$  between the last two, and we get

$$\xi(m_1\zeta - n_1\eta) = l_2\gamma\eta - l_2\beta\zeta \quad \dots \dots \dots (3).$$

Now introduce in (1), in the first of (2), and in (3), Rodrigues's values of the cosines (§ 83), and they become respectively

$$(yz - wx)\beta - (yz + wx)\gamma = 0,$$

$$(xz - wy)\eta - (xz + wy)\xi = (yz + wx)\beta - (yz - wx)\gamma,$$

$$\xi(wz + xy) - \xi\eta(xz - wy) = (xz + wy)\gamma\eta - (xy - wz)\beta\zeta.$$

Rearranging according to  $y, z$ , and  $yz$ ,

$$(\beta - \gamma)yz - (\beta + \gamma)wx = 0,$$

$$(\beta - \gamma)yz + (\eta\gamma + \xi\eta)y - (\eta\gamma - \xi\eta)z + (\beta + \gamma)wx = 0,$$

$$[\xi(\xi + \beta)x + \eta(\xi - \gamma)y] + [\xi(\xi - \beta)w - \eta(\xi + \gamma)z] = 0,$$

the second of which may be put, by means of the first, in the form

$$(w\eta + x\xi)y - (x\eta - w\xi)z + 2(\beta + \gamma)wx = 0.$$

These three equations involve  $w, x, y, z$  in the form of the ratios only of the last three to the first. The last two are linear in

$\frac{y}{w}, \frac{z}{w}$ . Solving them, and substituting in the first we find, finally, a biquadratic in  $\frac{x}{w}$ .

Hence, if particular values be assigned to  $\xi$ ,  $\eta$ ,  $\zeta$ , we find four values of  $\frac{x}{w}$ . Thus, in general, there are four positions of the single resultant force passing through any point.

But, without forming the biquadratic, we may easily obtain Minding's theorem. Suppose we seek the locus of all points in which the plane  $\xi\eta$  can be cut by the line of action of the single force. We have  $\zeta=0$ , and the equations above are reduced to

$$\begin{aligned}(\beta - \gamma)yz - (\beta + \gamma)wx &= 0, \\ \eta(wy - xz) + 2(\beta + \gamma)wx &= 0, \\ (\xi - \gamma)wy - (\xi + \gamma)xz &= 0.\end{aligned}$$

From the last two we find

$$\begin{aligned}-\gamma xz &= (\beta + \gamma)(\xi - \gamma)w, \\ -\gamma \eta y &= (\beta + \gamma)(\xi + \gamma)x,\end{aligned}$$

so that finally, by the first,

$$(\beta^2 - \gamma^2)(\xi^2 - \gamma^2) = \gamma^2 \eta^2,$$

or

$$\frac{\xi^2}{\gamma^2} - \frac{\eta^2}{\beta^2 - \gamma^2} = 1 \dots \dots \dots (4).$$

Had we put  $\eta=0$ , we should have found, by a similar process,

$$\frac{\xi^2}{\beta^2} + \frac{\zeta^2}{\beta^2 - \gamma^2} = 1 \dots \dots \dots (5).$$

(4) and (5) represent an hyperbola and an ellipse, or an ellipse and an hyperbola, respectively, according as  $\beta^2$  is greater or less than  $\gamma^2$ . In either case the vertices of the hyperbola coincide with the foci of the ellipse; so that the two curves are linked together.

It is now easy to see that, from any assigned point of space, the two curves will appear to intersect one another in four points. Two, or all, of these may in special cases coincide. Lines drawn to these points give the four positions of the single force which can pass through the assigned point.

### Examples of Statical Methods and Theorems.

**Ladder leaning against a wall.** § 229. Suppose a ladder to be leaning against a vertical wall. If there be no friction, what force, applied at the lower end, will just suffice to support it?

In the treatment of all questions of this kind the student should commence by making a rough sketch of the situation, indicating all the forces concerned, with the directions in which they act. As shown in fig. 62, the wall exerts an outward thrust  $S$  on the upper end of the ladder, the ground an upward thrust  $R$  on the lower end. The only other force is gravity, which may be supposed to produce a downward force at the middle of the ladder, equal to its whole weight. Unless there be some other horizontal force to balance  $S$ , the ladder will obviously slide down. Suppose then a horizontal force  $F$  to be applied

Fig. 62.

at the lower end, and let the ladder be inclined at an angle  $\alpha$  to the horizon. Then our conditions become horizontally  $S - F = 0$ , vertically  $W - R = 0$ , and for the couple in the plane of the figure,  $l$  being the length of the ladder,

$$\frac{1}{2}Wl \cos \alpha - Sl \sin \alpha = 0.$$

[The last equation is obtained by taking moments about the lower end of the ladder, this point being chosen (§ 217) because the directions of two of the forces pass through it.] From these equations we find at once

$$F = S = \frac{1}{2}W \cot \alpha.$$

It is to be observed that the requisite force  $F$  is very small while the ladder is nearly vertical, but increases without limit as it becomes more nearly horizontal.

Use of friction.

§ 230. Next let us vary the question by supposing the coefficient of friction on the ground to be  $\mu$ . The equations are precisely the same as before, and the limiting value of  $\alpha$  for which equilibrium is possible is now to be found by putting

$$\begin{aligned}F &= \mu R = \mu W, \\ 2\mu &= \cot \alpha.\end{aligned}$$

Thus

gives the smallest value of  $\alpha$  for which equilibrium is possible. For any larger value of  $\alpha$  less friction is called into play.

§ 231. If next we assume the wall also to be rough, a new friction force,  $G$ , comes in. The equations (for any given value of  $\alpha$ ) are

$$\begin{aligned}S - F &= 0, \\ W - R - G &= 0, \\ \frac{1}{2}Wl \cos \alpha - Sl \sin \alpha - Gl \cos \alpha &= 0.\end{aligned}$$

Here there is a certain amount of indeterminateness which our formulæ cannot escape (although of course it does not exist in nature) so long as we are not dealing with the limiting case in which motion is about to commence. In that case we have the additional conditions

$$G = \mu S, \quad F = \mu R.$$

Thus, in all, there are five equations. These are requisite and necessary because there are four forces  $S$ ,  $G$ ,  $R$ ,  $F$  to be determined, as well as the special value of the angle  $\alpha$ . The result of eliminating the four forces is

$$\tan \alpha = \frac{1 - \mu^2}{2\mu}.$$

§ 232. We may still further vary the question by sup- Man on posing a man of weight  $w$  to ascend the ladder. Let  $e$  ladder. represent the fraction of the ladder's length which he has ascended. The equations are

$$\begin{aligned}S - F &= 0, \\ W + w - R - G &= 0, \\ (\frac{1}{2}W + ew)l \cos \alpha_1 - Sl \sin \alpha_1 - Gl \cos \alpha_1 &= 0.\end{aligned}$$

Introducing the condition that slipping is just about to commence, we obtain

$$\frac{\tan \alpha_1}{\tan \alpha} = \frac{1 + 2\frac{w}{W} \frac{(1 + \mu^2)e - \mu^2}{1 - \mu^2}}{1 + \frac{w}{W}}.$$

where  $\alpha$  has the value given in § 231. Hence the limiting angle is increased or diminished by the load on the ladder according as

$$2(1 + \mu^2)e - 2\mu^2 \gtrless 1 - \mu^2,$$

i.e.,

$$2e \gtrless 1.$$

The ratio  $w/W$  does not appear in this condition. But it shows its importance when  $e$  is either greater or less than  $\frac{1}{2}$ .

Hence, when the ladder is just about to slip, a man makes it more stable if he stands anywhere on the lower half of it, but brings it down if he mounts higher. We conclude that, so far as sliding is concerned, it is advantageous to make the lower half of a ladder more massive than the upper half.

§ 233. Suppose a ladder, with its lower end resting against a wall, to be supported by a horizontal rail parallel to the wall (fig. 63). This case is chosen because it illustrates definite limits within which stability is ensured.

Let  $a$  be the half length of the ladder,  $\alpha$  its inclination to the horizon,  $b$  the distance of the rail from the wall. Suppose the ladder in such a position that if there were no friction it would slip downwards. Then the equations of equilibrium are

$$\begin{aligned}R + G \cos \alpha - S \sin \alpha &= 0, \\ F + S \cos \alpha + G \sin \alpha - W &= 0, \\ Sl \sec \alpha - W a \cos \alpha &= 0.\end{aligned}$$

Fig. 63.

In the third of these equations the lower end of the ladder has been chosen as the point about which moments are taken, because the lines of action of three of the forces

pass through it. Here again there is indeterminateness, because there are two places at which friction comes in, and we do not know at which it is most freely exerted. But if the whole be on the point of slipping, we have as before the additional data

$$F = \mu R, \quad G = \mu S.$$

These lead to the equation

$$(1 - \mu^2) \cos \alpha + 2\mu \sin \alpha = \frac{b}{a} \sec^2 \alpha.$$

If we introduce an angle  $\nu$  such that

$$\cos \nu = \frac{1 - \mu^2}{1 + \mu^2}, \quad \sin \nu = \frac{2\mu}{1 + \mu^2}$$

this equation becomes

$$\cos^2 \alpha \cos(\alpha - \nu) = \frac{b}{a(1 + \mu^2)} = \frac{b}{a} \cos^2 \frac{\nu}{2},$$

the right-hand member of which must necessarily be less than 1.

This determines the lowest position of the lower end consistent with equilibrium, and the mere change of sign of  $\mu$ , and therefore of  $\nu$ , alters it into the equation for the highest. The signs of the friction terms are changed when the direction of slipping is supposed to be reversed.

#### KINETICS OF A RIGID SOLID.

Rotation  
of rigid  
solid.

§ 234. The motion of a rigid body is, as we have seen, completely determined when we know the motion of one of its points and the relative motion of the body about that point. The point usually chosen is the centre of inertia of the body, and the investigation of its motion comes under the kinetics of a particle, which we have already sufficiently discussed. For we are permitted to suppose the whole mass to be concentrated at that point, and to be acted on by all the separate forces, each unaltered in direction and magnitude. Hence we may now confine ourselves to the study of the motion about the centre of inertia which, for the moment, we may look on as fixed.

To illustrate, in a very simple manner, the new conceptions which are required for the study of this question, let us take a uniform circular ring of matter, of radius  $R$ , revolving with angular velocity  $\omega$  about an axis through its centre, and perpendicular to its plane. Its moment of momentum is obviously

$$M \cdot R\omega \cdot R \text{ or } MR^2 \cdot \omega.$$

Its kinetic energy is

$$\frac{1}{2}M(R\omega)^2 \text{ or } \frac{1}{2}MR^2 \cdot \omega^2.$$

If it be acted on by a couple  $C$ , in its plane,  $C$  is the rate of increase of the moment of momentum, or

$$MR^2 \cdot \dot{\omega} = C.$$

The work done by the couple in time  $\delta t$  is

$$C\omega\delta t,$$

and the increase of kinetic energy is

$$MR^2 \cdot \omega\dot{\omega}\delta t.$$

By equating these we have (after dividing both sides by  $\omega$ ) the same equation as we obtained from the rate of increase of moment of momentum. It will be observed that these equations are of exactly the same form as those for the motion of a particle parallel to one of the coordinate axes, only that  $\omega$  takes the place of a velocity (such as  $\dot{x}$ ) while the expression  $MR^2$  takes the place of  $M$ , and the right-hand side is the moment of a force, not a force simply.

§ 235. Hence, generally, we define as follows:—

DEF. The “moment of inertia” of a body about any axis is the sum of the products of the mass of each particle of the body into the square of its (least) distance from the axis.

The following theorem enables us at once to find the

moment of inertia about any line, as axis, from that about a parallel axis through the centre of inertia.

Let the line be chosen as the axis of  $z$ , then the moment of inertia about it is

$$\Sigma m(x^2 + y^2).$$

But, if  $\bar{x}, \bar{y}$  be the coordinates of the centre of inertia,  $\xi, \eta$  the coordinates of  $m$  with reference to that centre, we have

$$x = \bar{x} + \xi, \quad y = \bar{y} + \eta,$$

and the above expression for the moment of inertia becomes

$$\Sigma m(\bar{x}^2 + \bar{y}^2 + 2\bar{x}\xi + 2\bar{y}\eta + \xi^2 + \eta^2).$$

By the property of the centre of inertia, § 109,

$$\Sigma(m\xi) = 0, \quad \Sigma(m\eta) = 0.$$

Hence the above expression consists of two parts:—

$$\Sigma m(\bar{x}^2 + \bar{y}^2)$$

the moment of inertia about a parallel axis through the centre of inertia, and

$$\Sigma(m) \cdot (\bar{x}^2 + \bar{y}^2)$$

the moment of inertia of the whole mass supposed concentrated at its centre of inertia.

§ 236. Hence we need study only the moments of inertia about axes passing through the centre of inertia. But we will commence with an origin assumed at hazard.

If the direction cosines of an axis through the origin be  $\lambda, \mu, \nu$ , the square of the distance of the mass  $m$  at  $x, y, z$  from it is

$$x^2 + y^2 + z^2 - (\lambda x + \mu y + \nu z)^2.$$

Hence the moment of inertia is

$$\begin{aligned} \mathfrak{I} &= \Sigma m(x^2 + y^2 + z^2 - (\lambda x + \mu y + \nu z)^2) \\ &= \Sigma m((y^2 + z^2)\lambda^2 + (x^2 + z^2)\mu^2 + (x^2 + y^2)\nu^2 - 2xy\lambda\mu - 2yz\mu\nu - 2xz\nu\lambda), \end{aligned}$$

which may be written

$$\mathfrak{I} = A\lambda^2 + 2G_3\lambda\mu + B\mu^2 + 2G_1\mu\nu + 2G_2\nu\lambda + C\nu^2.$$

If we measure off, on the axis, a quantity  $\rho$  whose square is the reciprocal of  $\mathfrak{I}$ , and call its terminal coordinates  $\xi, \eta, \zeta$ , this equation becomes by multiplying both sides by  $\rho^2$

$$1 = A\xi^2 + 2G_3\xi\eta + B\eta^2 + 2G_1\eta\zeta + 2G_2\zeta\xi + C\zeta^2.$$

As the moment of inertia is essentially a positive quantity, this equation represents an ellipsoid. It must of course have three principal axes; and, when these are taken as the coordinates axes, the terms in  $\xi\eta$ ,  $\eta\zeta$ , and  $\zeta\xi$  in the above expression must disappear.

§ 237. Hence at every point of every rigid body there are three “principal axes” of inertia, at right angles to one another. One of them is the axis of absolute maximum moment, another that of absolute minimum.

Our equation now becomes, when referred to these axes,

$$1 = A\xi^2 + B\eta^2 + C\zeta^2,$$

or, dividing by  $\rho^2$ ,

$$\mathfrak{I} = A\lambda^2 + B\mu^2 + C\nu^2.$$

Thus the moment of inertia about any axis is found from those about the principal axes at that point by multiplying each by the square of the corresponding direction cosine, and adding the results.

For the quantity  $A$  was written originally as

$$\Sigma m(y^2 + z^2),$$

i.e., it is the moment of inertia about the axis of  $x$ . We see also that, at every point of a body, there are three rectangular axes such that the expressions

$$\Sigma(mxyz), \quad \Sigma(myz), \quad \Sigma(mzx)$$

vanish when these are taken as coordinate axes.

To find how these axes are distributed in a body, let us suppose it referred to the principal axes through its centre of inertia, and let  $Mk_1^2, Mk_2^2, Mk_3^2$  be the moments of inertia about them. The principal quantities  $k_1, k_2, k_3$  are called the principal “radii of gyration.” axes. Then, by the results above, the moment of inertia about a line through the point  $\alpha, \beta, \gamma$  is

$$\mathfrak{I} = M\{\alpha^2 + \beta^2 + \gamma^2 - (\lambda\alpha + \mu\beta + \nu\gamma)^2\} + M(\lambda^2 k_1^2 + \mu^2 k_2^2 + \nu^2 k_3^2).$$

For a principal axis this is to be a maximum or minimum, with the sole condition

$$\lambda^2 + \mu^2 + \nu^2 = 1.$$

Moment  
of iner-  
tia.

of gyra-  
tion.

Hence, if  $p$  be an undetermined multiplier, we have

$$\begin{aligned}(k_1^2 + p)\lambda - \alpha(\alpha\lambda + \beta\mu + \gamma\nu) &= 0, \\ (k_2^2 + p)\mu - \beta(\alpha\lambda + \beta\mu + \gamma\nu) &= 0, \\ (k_3^2 + p)\nu - \gamma(\alpha\lambda + \beta\mu + \gamma\nu) &= 0.\end{aligned}$$

But, if we consider a surface of the second order

$$\frac{x^2}{k_1^2 + p} + \frac{y^2}{k_2^2 + p} + \frac{z^2}{k_3^2 + p} = 1,$$

confocal with the ellipsoid

$$\frac{x^2}{k_1^2} + \frac{y^2}{k_2^2} + \frac{z^2}{k_3^2} = 1, \quad \dots \dots \dots (a),$$

the direction cosines of its normal at  $x, y, z$  are

$$\lambda : \mu : \nu :: \frac{x}{k_1^2 + p} : \frac{y}{k_2^2 + p} : \frac{z}{k_3^2 + p}.$$

Hence, if this surface pass through the point  $\alpha, \beta, \gamma$ , we have

$$\begin{aligned}(k_1^2 + p)\lambda &= P\alpha, \\ (k_2^2 + p)\mu &= P\beta, \\ (k_3^2 + p)\nu &= P\gamma,\end{aligned}$$

where  $P$  is determined by the equation

$$\alpha\lambda + \beta\mu + \gamma\nu = P \left( \frac{\alpha^2}{k_1^2 + p} + \frac{\beta^2}{k_2^2 + p} + \frac{\gamma^2}{k_3^2 + p} \right) = P.$$

Substitute this value of  $P$  in the preceding equations, and they become identical with those above given for determining the principal axes at  $\alpha, \beta, \gamma$ . Hence Binet's Theorem:—

*The principal axes at any point of a body are normals to the three surfaces of the second order which pass through that point and are confocal with the ellipsoid (a).*

Principal moments of inertia. § 238. We will here tabulate the values of the moments of inertia about principal axes through the centre of inertia, in a few specially useful cases.

1. Plane uniform circular disk.

Divide it into concentric rings, of radius  $r$ , of breadth  $\delta r$ . Then the moment of inertia about the axis through the centre, and perpendicular to the plane, of the circle is

$$\rho \int_0^a 2\pi r^3 \delta r = \frac{1}{2} \pi a^4 \rho,$$

where  $a$  is the radius, and  $\rho$  the mass of a square unit, of the disk.

But the mass is  $\pi a^2 \rho$ ,

so that

$$k_z^2 = \frac{1}{2} a^2.$$

This of course, applies to a circular cylinder. Obviously, in the disk

$$k_z^2 = k_x^2 = k_y^2 = \frac{1}{2} a^2.$$

In fact the moment of inertia about an axis drawn perpendicular to any plane figure at any point is equal to the sum of the other two about rectangular axes which lie in the plane. The one is  $\Sigma m(x^2 + y^2)$ , and the others are  $\Sigma m x^2$  and  $\Sigma m y^2$  respectively.

2. Uniform rod of length  $l$ ,  $\rho$  mass per unit length.

$$M = l\rho, \quad Mk_1^2 = 0, \quad Mk_2^2 = Mk_3^2 = 2\rho \int_0^l x^2 dx = \frac{\rho l^3}{12},$$

so that

$$k_2^2 = k_3^2 = \frac{1}{12} l^2.$$

3. Uniform rectangular plate, sides  $a$  and  $b$ , axis parallel to  $b$ .

$$Mk^2 = 2b\rho \int_0^a x^3 dx = \frac{\rho a^3 b}{12},$$

so that

$$k_1^2 = \frac{1}{12} a^2, \quad \text{and} \quad k_2^2 = \frac{1}{12} b^2.$$

Hence, by the remark above,

$$k_z^2 = \frac{1}{12} (a^2 + b^2).$$

4. Uniform sphere, radius  $a$ ,  $\rho$  mass per unit volume. Here

$$\Sigma m(x^2 + y^2) = \Sigma m x^2,$$

and therefore the sum of any two is

$$= \frac{2}{3} \Sigma m(x^2 + y^2 + z^2).$$

Thus

$$Mk_1^2 = Mk_2^2 = Mk_3^2 = \frac{2}{3} \Sigma m r^2 = \frac{2}{3} \rho \int_0^a r^4 dr = \frac{8}{15} \pi \rho a^5.$$

But

$$M = \frac{4}{3} \pi \rho a^3,$$

and thus

$$k_1^2 = k_2^2 = k_3^2 = \frac{8}{15} a^2.$$

5. Plane uniform elliptic disk, semiaxes  $a, b$ ;  $\rho$  mass of unit area. Moment of inertia about  $a$  is

$$Mk_1^2 = 2\rho \int_0^a \frac{y^3}{3} dx = \frac{\pi a b^3 \rho}{4},$$

so that

$$k_1^2 = \frac{1}{4} b^2.$$

From this follows immediately

6. Ellipsoid, semiaxes  $a, b, c$ , and of uniform density:—

$$k_1^2 = \frac{1}{5} (b^2 + c^2), \quad k_2^2 = \frac{1}{5} (c^2 + a^2), \quad k_3^2 = \frac{1}{5} (a^2 + b^2).$$

From these we can, of course, reproduce the result for a sphere.

7. Rectangular parallelepiped, edges  $a, b, c$ :—

$$k_1^2 = \frac{1}{12} (b^2 + c^2), \quad k_2^2 = \frac{1}{12} (c^2 + a^2), \quad k_3^2 = \frac{1}{12} (a^2 + b^2).$$

The determination of moments of inertia is, like that of centres of inertia, a purely mathematical matter, the full discussion of which would lead us away from the proper objects of this article.

§ 239. The simplest cases that can present themselves so far as rotation is concerned (for the translational effects on a rigid body are treated precisely as if it were a mere particle,—a process already sufficiently illustrated) are those in which there is one degree of freedom to rotate, *i.e.*, when the body is rigidly attached to a fixed axis. Here the physical condition is simply that the rate of increase of moment of momentum is equal to the moment of the resultant couple about the axis of rotation.

§ 240. Let us recur to Atwood's machine as a first example, and suppose the string not to slip on the pulley, so that the pulley must turn. In this case we must observe that the two free parts of the string are now, as it were, separate strings, so that we have no right to assume their tensions to be equal. In fact if they were equal there would be no acceleration of the rotation of the pulley, nor of course of the common velocity of the two masses. We assume that the pulley is symmetrical, and the axis through its centre of inertia.

Let  $a$  be the radius of the pulley, and  $\omega$  its angular velocity, then  $a\omega$  is the linear velocity of either mass. Thus the linear acceleration of each of the masses is equal to  $a$  times the angular acceleration of the pulley. But the linear acceleration multiplied by the mass is the measure of the force producing it; while the angular acceleration multiplied by the moment of inertia is the measure of the moment of the couple producing it. Thus we have ( $M$  being the mass of the pulley, and  $k$  its radius of gyration)

$$\begin{aligned}Mk^2 \times \text{angular acceleration} &= (T' - T)a, \\ m' \times \text{linear acceleration} &= m'g - T', \\ m \times \text{linear acceleration} &= T - mg.\end{aligned}$$

Eliminating  $T$  and  $T'$ , and taking account of the above relation between the accelerations, we find at once

$$\text{Linear Acceleration} = \frac{m' - m}{m' + m + Mk^2/a^2} g;$$

from which, by the last two of our equations, the separate values of  $T$  and  $T'$  may be found.

If we compare this result with that obtained in § 173, on the supposition that the pulley was perfectly smooth, we see that the only difference is in the addition of  $Mk^2/a^2$  to the sum of the two masses. Otherwise the nature of the motion remains unaffected.

§ 241. Let us next take the case of a body of any form attached to a horizontal axis which does not pass through its centre of inertia. In such a case gravity is the force producing motion, and we have what is called a "compound pendulum." Draw through the centre of inertia a line parallel to the axis; let  $h$  be the distance between these lines, and  $\theta$  the angle which their plane makes (at a given time) with the vertical. The moment producing angular acceleration is obviously

$$- mgh \sin \theta.$$

Divide by the moment of inertia about the axis, which by a previous proposition (§ 235) is

$$m(k^2 + h^2)$$

(where  $k$  is the radius of gyration about the line drawn through the centre of inertia), and we have for the angular acceleration

$$-\frac{gh \sin \theta}{k^2 + h^2}.$$

In the case of a simple pendulum of length  $l$ , we saw that the angular acceleration is

$$-\frac{g \sin \theta}{l}.$$

Hence the motion of the compound pendulum will be identical with that of the simple pendulum when, and only when,

$$l = \frac{k^2 + h^2}{h} = 2k + \frac{(k-h)^2}{h}.$$

As  $h$  and  $k$  are necessarily positive (or rather *signless*) quantities, the smallest value of  $l$  is evidently when  $k=h$ . Hence the shortest time in which the mass can vibrate about any axis parallel to the original one corresponds to that of a simple pendulum of length  $2k$ . When  $h$  is made either less or greater than  $k$ , the length of the equivalent simple pendulum increases, and for any assigned value of  $l$  greater than  $2k$  there are two corresponding values of  $h$ , one less and the other greater than  $k$ . Their sum, however, as we see by the coefficient of the second term in the equation

$$h^2 - 2kh + k^2 = 0,$$

is always equal to  $l$ .

If then we can find two parallel axes in a rigid body, lying in one plane with the centre of inertia, and on opposite sides of that point, such that the time of oscillation is the same for each, the distance between them is the length of the equivalent simple pendulum. Kater made use of this proposition in his determination of the length of the second's pendulum, under the circumstances in which it was defined by Act of Parliament as a datum for restoring, in case of loss, the standard yard.

Complex compound pendulum.

§ 242. Suppose now that a second body is attached to the first by an axis parallel to that about which the first is constrained to move; and, for simplicity, suppose the centre of inertia of the first body to be in the plane containing the two axes. Here we have a *complex compound pendulum*, and it is interesting to compare the motion with that of the complex simple pendulum of §§ 177, 178.

Let  $m'$ ,  $h'$ ,  $\phi$  correspond, for the second body, to  $m$ ,  $h$ ,  $\theta$  for the first, and let  $a$  be the distance between the axes. For variety we will adopt Lagrange's method. We have clearly

$$T = \frac{1}{2} (mk^2\dot{\theta}^2 + mh^2\dot{\theta}^2 + m'k'^2\dot{\phi}^2 + m'(a^2\dot{\theta}^2 + h'^2\dot{\phi}^2 + 2ah'\cos(\phi - \theta)\dot{\theta}\dot{\phi})),$$

$$V = C - mgh\cos\theta - m'g(a\cos\theta + h'\cos\phi).$$

These would enable us at once to write down the equations of motion, however large be the disturbance, but they are too complex for our present work. Let us then assume  $\phi$  and  $\theta$  to be very small, and we have

$$\begin{aligned} \{m(k^2 + h^2) + m'a^2\}\ddot{\theta} + m'ah'\ddot{\phi} &= -(m\dot{h} + m'a)g\theta, \\ m'(k'^2 + h'^2)\ddot{\phi} + m'ah'\ddot{\theta} &= -m'gh'\phi. \end{aligned}$$

Combining, as before, by means of an undetermined multiplier, we have

$$\begin{aligned} (m(k^2 + h^2) + m'a^2 + \lambda m'ah')\ddot{\theta} + (m'ah' + \lambda m'(k'^2 + h'^2))\ddot{\phi} \\ = -g\{(m\dot{h} + m'a)\theta + \lambda m'h'\phi\}. \end{aligned}$$

Thus the two values of  $\lambda$  are given by the equation

$$\frac{m'ah' + \lambda m'(k'^2 + h'^2)}{m(k^2 + h^2) + m'a^2 + \lambda m'ah'} = \frac{\lambda m'h'}{m\dot{h} + m'a}.$$

This may be written in the form

$$\frac{A + \lambda}{B + \lambda} = \frac{\lambda}{C},$$

where  $B$  is greater than  $A$ ; and  $A$ ,  $B$ ,  $C$  are all essentially positive, if the bodies have been only slightly displaced from the position of stable equilibrium. The equation gives

$$\lambda^2 + (B - C)\lambda - AC = 0,$$

so that the values of  $\lambda$  are essentially real and of opposite signs. If we write  $\mu = B$  for  $\lambda$ , this equation becomes

$$\mu^2 - (B + C)\mu + (B - A)C = 0,$$

so that the values of  $\lambda + B$  are both positive, and therefore the motion of either mass is the resultant of two simple harmonic motions.

§ 243. A well-known puzzle in connexion with this subject

used to be "How to distinguish between two hollow shells, Rolling one of gold the other of silver, if their diameters and masses of hollow be alike, and both be painted." If we observe that the volumes of equal masses are inversely as the densities, the volume of the gold shell is seen to be less than that of the silver one, and therefore, on the whole, its mass is farther from the centre, and its moment of inertia greater. Hence any form of experiment in which the moment of inertia comes in will suffice to decide the question. Thus they might be alternately clamped tight to the end of a rod, and the system swung as a pendulum, when the gold sphere would vibrate more slowly than the silver one. Or they might be allowed to *roll*, not *slide*, down a rough plane. In this case the work done by gravity on each is the same when they have fallen through equal spaces. But its equivalent is in the form of kinetic energy, partly translational and partly rotational. The relative amounts of these two depend on the moments of inertia of the spheres, for the ratio of the translational velocity to the angular velocity is the same for each. Hence the gold sphere, having the greater moment of inertia, will have the smaller velocity of translation. Another form of this question was to have a shell with a spherical mass inside, which might be either free to rotate on gimbals, or else be keyed to the outer skin. The keying would of course retard the motion of the whole down a rough plane, for part of the energy due to gravity would then be shared by the internal mass in the form of energy of rotation, from which it would otherwise have been free. Another very instructive form is that of a spherical shell full of fluid. If the fluid be perfect, the moment of inertia is that of the shell alone; if it be infinitely viscous, the moment of inertia is that of shell and fluid as if they constituted one rigid solid; and we may have every intermediate amount. If we suppose the rotation of the outer shell to be suddenly stopped, the infinitely viscous contents would be reduced to rest also. But if they be not infinitely viscous they will not at once be brought to rest, but will be able to put the shell in rotation again if it be at once set free. Thus, in practice, we can tell a raw egg from a hard-boiled egg. The first is with difficulty made to rotate, and sets itself in motion again if it be stopped and at once let go. The second behaves, practically, like a rigid solid.

§ 244. The problem of the rolling of a sphere down a rough inclined plane is solved at once, as above, by applying the conservation of energy. For, if  $x$  be the coordinate of its centre parallel to the plane,  $\theta$  the angle through which it has turned, and  $a$  its radius, we have the kinematical condition

$$x = a\theta$$

(due to the perfect roughness of the plane).

Also the potential energy lost is

$$Mgx \sin \alpha,$$

where  $\alpha$  is the inclination of the plane to the horizon; and the kinetic energy gained is made up of the two parts, —  $\frac{1}{2}M\dot{x}^2$  translational, and  $\frac{1}{2}Mk^2\dot{\theta}^2$  rotational.

Hence

$$M(k^2 + a^2)\dot{\theta}^2 = 2Mga\theta \sin \alpha,$$

or

$$\dot{x}^2 = 2 \frac{a^2 g}{k^2 + a^2} x \sin \alpha.$$

This shows that the motion is the same as that of a particle sliding down a *smooth* plane of the same inclination, under gravity diminished in the ratio  $a^2 : k^2 + a^2$ . And it shows how friction may retard motion without producing any dissipation of energy.

§ 245. Suppose one point of a rigid plane sheet be made to move in any manner in the plane of the sheet, what will be the consequent rotation?

Let  $M$  be the mass, and  $\xi$ ,  $\eta$ , given in terms of  $t$ , the coordinates

Varying of the point of the sheet whose motion is assigned. Let  $\alpha, \theta$  be the relative polar coordinates of the centre of inertia, then

$$M[\ddot{\xi} + \alpha(\cos \theta)] = X, \quad M[\ddot{\eta} + \alpha(\sin \theta)] = Y,$$

$$Mk^2\ddot{\theta} = -Y\alpha \cos \theta + X\alpha \sin \theta;$$

where  $X$  and  $Y$  are the forces requisite to produce the motion. Eliminating them, we find

$$(k^2 + \alpha^2)\ddot{\theta} = -\alpha(\eta \cos \theta - \xi \sin \theta),$$

with which we can do no more until further data are specified.

Suppose  $\xi, \eta$  to move with uniform acceleration  $p$  in a direction assigned by  $\alpha$ , then

$$\xi = p \cos \alpha, \quad \eta = p \sin \alpha, \quad \text{and}$$

$$(k^2 + \alpha^2)\ddot{\theta} = -\alpha p (\sin \alpha \cos \theta - \cos \alpha \sin \theta) = \alpha p \sin(\theta - \alpha).$$

The centre of inertia of the mass therefore moves, relatively to the constrained point, precisely as does a simple pendulum; but the direction of  $p$  is reversed.

Again suppose the constrained point to move uniformly in a circle of radius  $b$ , with angular velocity  $\omega$ . We have

$$\xi = b \cos \omega t, \quad \eta = b \sin \omega t,$$

and  $(k^2 + \alpha^2)\ddot{\theta} = +\omega^2 ab (\sin \omega t \cos \theta - \cos \omega t \sin \theta),$

or  $(k^2 + \alpha^2)\left(\frac{d}{dt}\right)^2(\theta - \omega t) = -\omega^2 ab \sin(\theta - \omega t).$

This is, again, the equation of motion of a simple pendulum, but the angle of displacement  $\theta - \omega t$  is no longer measured from a fixed line but from the uniformly rotating radius of the guide circle. Hence the mass oscillates, pendulum-wise, about this uniformly revolving line.

§ 246. Let us take, as an instance of impulse, the case of Robins's "ballistic pendulum,"—a massive block of wood movable about a horizontal axis at a considerable distance above it,—employed to measure the velocity of a cannon or musket shot. The shot is usually fired into the block in a horizontal direction perpendicular to the axis. The impulsive penetration is so nearly instantaneous, and the mass of the block so large compared with that of the shot, that the ball and pendulum are moving on as one mass before the pendulum has been sensibly deflected from the position of equilibrium. This is the essential peculiarity of the ballistic method,—which is used also extensively in electromagnetic researches and in practical electric testing, when the integral quantity of the electricity which has passed in a current of short duration is to be measured. The line of motion of the bullet at impact may be in any direction whatever, but the only part which is effective is the component in a plane perpendicular to the axis. We may therefore, for simplicity, consider the motion to be in a line perpendicular to the axis, though not necessarily horizontal.

Let  $m$  be the mass of the bullet,  $v$  its velocity, and  $p$  the distance of its line of motion from the axis. Let  $M$  be the mass of the pendulum with the bullet lodged in it, and  $k$  its radius of gyration. Then, if  $\omega$  be the angular velocity of the pendulum when the impact is complete,

$$mvp = Mk^2\omega,$$

from which the solution of the question is easily determined. For the kinetic energy after impact is changed into its equivalent in potential energy when the pendulum reaches its position of greatest deflexion. Let this be given by the angle  $\theta$ ; then the height to which the centre of inertia is raised is  $h(1 - \cos \theta)$ , if  $h$  be its distance from the axis. Thus

$$Mgh(1 - \cos \theta) = \frac{1}{2}Mk^2\omega^2 = \frac{1}{2}\frac{m^2v^2p^2}{Mk^2},$$

$$\text{or} \quad 2\sin \frac{\theta}{2} = \frac{m}{M} \frac{p}{k} \frac{v}{\sqrt{gh}},$$

an expression for the chord of the angle of deflexion. In practice the chord of the angle  $\theta$  is measured by means of a light tape or cord attached to a point of the pendulum, and slipping with small friction through a clip fixed close to the position occupied by that point when the pendulum hangs at rest.

§ 247. As another example of impulse let us consider the case of a body moving in any way in a plane perpendicular to one of its principal axes. It is required to find what point of the body must be suddenly fixed in order that the whole may be brought to rest; also, what will be the consequent

impulsive pressure at this point. It is easy to see that Impulse this is exactly the same question as to find the impulse, required and its point of application, so that it may produce a given motion of a body in a plane perpendicular to one of its principal axes.

The impulse must obviously act in a plane passing through the centre of inertia. And the physical conditions are that the change of momentum of translation is equal to, and in the direction of, the impulse, while the change of moment of momentum about the centre of inertia is equal to the moment of the impulse. Let the impulse acting at the point  $\xi, \eta$  have components  $R, S$  parallel to rectangular coordinates in the plane of motion, and let  $\omega$  be the angular velocity,  $u, v$  the linear velocities, generated by it. Then the physical conditions are

$$Mu = R, \quad Mv = S, \quad Mk^2\omega = S\xi - R\eta.$$

When  $u, v, \omega$  are given,  $R$  and  $S$  are found from the first two equations, and the third is then the equation of the line in which the impulse must act. Similarly, when the impulse and its line of action are given, we have in terms of these data the quantities  $u, v, \omega$ .

§ 248. As a simple practical example, suppose one strikes Centre of a hard object with a stick in such a way that his hand is at percussion. rest at the instant of the impact; with what part of the stick must he strike so that there may be no jar on his hand?

Let  $\xi$  be measured along the stick from its centre of inertia in the direction which it has at the instant of impact. Then the kinematical condition is

$$v = a\omega,$$

where  $a$  is the distance from the hand to the centre of inertia of the stick. Thus, as the impulse  $S$  is the sole cause of the stick's being brought to rest, we have

$$Mv + S = 0, \quad Mk^2\omega/a + S\xi = 0;$$

so that

$$\xi = k^2/a.$$

Hence if the stick be uniform and be held by one end, so that its length is  $2a$ , and therefore  $3k^2 = a^2$ , we have

$$\xi = \frac{1}{3}a;$$

and  $a + \xi$ , the distance of the point of impact from the hand, is

$$a + \frac{1}{3}a = \frac{4}{3}a,$$

i.e., it is at two-thirds of the length of the stick.

If, however, the hand be moving, at the instant of impact, perpendicularly to the stick with velocity  $V$ , the kinematical condition is  $v - V = a\omega$ , which introduces a corresponding change in the result.

§ 249. The reaction of the axis is easily calculated. If Reaction the axis about which the body is constrained to rotate on axis. be perpendicular to a plane through the centre of inertia about which the body is symmetrical, and if the applied forces act in that plane, it is clear that the reaction of the axis is a single force in that plane. Let its components be  $\Xi$  and  $H$ . Then

$$\Sigma(m\dot{x}) = \Sigma(X) + \Xi, \quad \Sigma(m\dot{y}) = \Sigma(Y) + H,$$

$$\Sigma m(x\dot{y} - y\dot{x}) = \Sigma(xY - yX).$$

Let  $\alpha, \theta$ , be the polar coordinates of the centre of inertia, then  $\dot{\theta}, \ddot{\theta}$  are the angular velocity and the angular acceleration for all particles of the mass, and we have

$$-Macos\theta.\dot{\theta}^2 - Masin\theta.\ddot{\theta} = \Sigma(X) + \Xi,$$

$$Masin\theta.\dot{\theta}^2 + Macos\theta.\ddot{\theta} = \Sigma(Y) + H,$$

$$M(k^2 + \alpha^2)\ddot{\theta} = \Sigma(xY - yX).$$

From the third we find  $\ddot{\theta}$ , and the others give  $\Xi$  and  $H$ .

When there is no plane of symmetry perpendicular to the axis, there must be two points of it at which reactions are exerted on the revolving body. Let the coordinates of these bearings be  $c, c'$ , and the reactions there  $\Xi, H, Z, \Xi', H', Z'$  respectively.

Then we have the six equations (in which  $\ddot{z}=0$ )

$$\begin{aligned}\Sigma(m\ddot{x}) &= \Sigma(X) + \Xi + \Xi', \\ \Sigma(m\ddot{y}) &= \Sigma(Y) + H + H', \\ \Sigma(m\ddot{z}) &= \Sigma(Z) + Z + Z'; \\ \Sigma m(xy - yx) &= \Sigma(xY - yX), \\ \Sigma m(y\ddot{z} - z\ddot{y}) &= \Sigma(yZ - zY) - cH - c'H', \\ \Sigma m(z\ddot{x} - x\ddot{z}) &= \Sigma(zX - xZ) + c\Xi + c'\Xi'.\end{aligned}$$

The fourth equation, as before, determines  $\theta$ , and we have then four equations to determine  $\Xi, \Xi', H, H'$ . The remaining equation determines only the sum  $Z + Z'$ . In fact by more or less perfect fitting we can throw more or less of the force parallel to the axis on one or other of the bearings. There is really no indeterminateness in nature, but we cannot get the information required to evaluate separately  $Z$  and  $Z'$ .

§ 250. When impulsive forces are applied to the body, exactly the same methods may be employed, with the exception that  $u' - u$  must be written for  $\dot{x}$ , &c., and  $\omega' - \omega$  for  $\dot{\theta}$ . The quantities  $X, Y, Z, \Xi, H, Z, \Xi', H', Z'$  now denote impulses and not forces.

As a single example of the use of these formulæ, take the case of a body rotating, under the action of no force, about an axis through its centre of inertia. Here  $\Sigma(m\ddot{x})=0$ , &c., and  $z$  is constant. The first two of the six equations last written show that the pairs of forces  $\Xi, \Xi'$  and  $H, H'$  form couples. The fourth equation gives  $\theta = \omega t$ ; and with this the remaining two become

$$\begin{aligned}\Sigma(mzy) \cdot \omega^2 &= -cH - c'H' = -(c - c')H, \\ \Sigma(mzx) \cdot \omega^2 &= -c\Xi - c'\Xi' = -(c - c')\Xi.\end{aligned}$$

The multipliers of  $\omega^2$  are each zero if the axis of rotation be a principal axis, and thus, in this case, there is no stress perpendicular to the axis. When the axis is not a principal axis the left hand terms are generally finite but they vary as the body turns. It is easy to see, however, that together these terms constitute a constant couple always in a plane passing through the axis, rotating with the body and dependent directly on the square of the angular velocity. Thus, to analyse the factor  $\Sigma(mzy)$ , we note that  $z$  is constant, and

$$y = r \sin(\omega t + \alpha),$$

where  $r, \alpha$  were the polar coordinates of the mass  $m$  at time  $t=0$ .

Hence  $\Sigma(mzy) = \sin \omega t \Sigma(mzx_1) + \cos \omega t \Sigma(mzy_1)$ ,

where  $x_1 = r \cos \alpha$  and  $y_1 = r \sin \alpha$  were the coordinates of  $m$  at  $t=0$ .

Similarly we have

$$\Sigma(mzx) = \cos \omega t \Sigma(mzx_1) - \sin \omega t \Sigma(mzy_1).$$

These expressions prove the preceding statements.

§ 251. As a final instance of impulse in this branch of the subject, suppose that a rigid plate, moving anyhow in its own plane, has one of its points suddenly fixed, what will be the subsequent motion? Let the position in space at which the point is to be fixed be chosen as origin, and let the axis of  $x$  be chosen so as to pass through the centre of inertia at the moment of fixture. Then, if  $u, v$  be the velocities of the centre of inertia,  $\omega$  the angular velocity about it,  $a$  its distance from the point to be fixed, the conditions of the impact are

$$\begin{aligned}u' &= u - \Xi/M, \\ v' &= v - H/M, \\ \omega' &= \omega + Ha/Mk^2,\end{aligned}$$

—three equations with five unknown quantities. But the conditions that the point in question is reduced to rest are evidently

$$u' = 0, \quad v' - \omega'a = 0.$$

These furnish the requisite additional data, and the solution is complete. If we eliminate  $H$  between the two equations which contain it, we have

$$k^2\omega' + av' = k^2\omega + av,$$

whence by the relation between  $v'$  and  $\omega'$  we have

$$(k^2 + a^2)\omega' = k^2\omega + av.$$

These equal quantities, each multiplied by  $M$ , represent respectively the moment of momentum about the point before and after its fixture.

§ 252. Thus, as a little consideration will show, we might have solved the problem at once, so far as the impulsive change of motion is concerned, by noticing that as the im-

pulse is applied at the origin, the moment of momentum about that point will not be altered by it. In fact many problems, which present serious complexity when treated by the direct methods, are solved with comparative ease by such general considerations as the conservation of moment of momentum, or the conservation of energy. The first principle holds good when there is no resultant couple, or impulsive couple, round the origin; the second when no work on the whole is done by or against the forces or impulses.

§ 253. We have given instances of pure sliding, and of combined pure rolling, in one plane, and will now give a single instance of combined rolling and sliding. A common but instructive case of the problem we propose to consider is that of a hoop thrown forwards and at the same time made to rotate, so that after a time it stops, and finally rolls backwards to the hand. Other cases are furnished by a "following stroke" or a "screw-back" with a billiard ball.

Let the axis of  $x$  be parallel to the motion of translation of a sphere or cylinder moving on a horizontal plane. Then we have, if  $F$  be the friction,  $a$  the radius of the hoop or ball, the rate of change of momentum  $= F$ , and that of moment of momentum about the centre  $= Fa$ .

So long as sliding continues,  $F$  is constant, and equal to the product  $\mu Mg$  of the normal pressure and the coefficient of kinetic friction. Hence at time  $t$ , if  $u_0$  and  $\omega_0$  be the initial velocities of translation and of rotation,

$$\begin{aligned}u &= u_0 - \mu gt, \\ k^2\omega &= k^2\omega_0 - \mu gat.\end{aligned}$$

These equations cease to be true when the sliding ceases, i.e., when we have pure rolling, of which the geometrical condition is

$$u + a\omega = 0.$$

This gives

$$u_0 + a\omega_0 - \mu g(a^2/k^2 + 1)t_0 = 0,$$

or

$$t_0 = \frac{k^2(u_0 + a\omega_0)}{\mu g(a^2 + k^2)}.$$

At time  $t$ , and ever after we have

$$\begin{aligned}u &= u_0 - \frac{k^2(u_0 + a\omega_0)}{k^2 + a^2} = a \frac{au_0 - k^2\omega_0}{k^2 + a^2}, \\ \omega &= \omega_0 - \frac{au_0 + a^2\omega_0}{k^2 + a^2} = \frac{k^2\omega_0 - au_0}{k^2 + a^2}.\end{aligned}$$

Hence, if the body be projected in the positive direction, its ultimate motion will be in the negative direction if  $au_0 - k^2\omega_0$  be negative, i.e., if the initial angular velocity be positive, and greater than  $au_0/k^2$ ; which is  $\frac{5}{2}u_0/a$  in the case of a sphere. Thus, at starting, the linear velocity of the point of contact with the plane must bear to that of translation of the ball a ratio of over 7 : 2 if it is to stop and return. In the case of a hoop this ratio must be at least 2 : 1.

§ 254. We pass now to the case of a rigid body one point only of which is fixed. As we have already seen (§ 234) this has only to be compounded with the motion of the whole mass, supposed concentrated at the point, in order to give the most general motion of which a rigid body is capable. The geometrical processes which have been applied to this problem, though in many respects of great power and elegance, cannot be introduced here. We will therefore give the more important results in a brief analytical form, and then geometrically exhibit their application.

Recurring to the general equations

$$\Sigma m(xy - yx) = \Sigma(xY - yX) = N, \text{ \&c.,}$$

we may transform the left hand members as follows.

Let  $\omega_x, \omega_y, \omega_z$  be the angular velocities of the body about the fixed axes of  $x, y, z$  respectively. Then (§ 77) we have

$$\dot{x} = z\omega_y - y\omega_z, \text{ \&c.}$$

From these we have three equations of the type

$$\begin{aligned}\dot{x} &= z\omega_y - y\omega_z + z\omega_y - y\omega_z \\ &= z\omega_y - y\omega_z + (y\omega_z - z\omega_y)\omega_y - (z\omega_y - y\omega_z)\omega_z.\end{aligned}$$

Thus we have

$$x\ddot{y} - y\ddot{x} = (x^2 + y^2)\dot{\omega}_z - 2x\dot{\omega}_x\dot{\omega}_y - 2y\dot{\omega}_y\dot{\omega}_x + 2x\dot{\omega}_x\dot{\omega}_z - 2y\dot{\omega}_y\dot{\omega}_z + (x^2 - y^2)\omega_x\omega_y - xy(\omega_x^2 - \omega_y^2).$$

Now if the fixed axes be taken so as to coincide at a particular instant with the principal axes of the body passing through the point which is regarded as fixed, the terms involving factors of the form  $\Sigma(mxy)$ , &c., necessarily vanish (§ 237). Also we have

$$\Sigma m(x^2 - y^2) = \Sigma m(x^2 + z^2 - y^2 - z^2),$$

so that, if the principal moments of inertia of the body be  $A, B, C$  respectively, the dynamical equations become

$$C\dot{\omega}_z + (B - A)\omega_x\omega_y = N, \text{ \&c.}$$

But it was proved in § 79 that when the angular velocities of a rigid body are referred to moving and to fixed axes, which coincide at a particular instant, not only are the angular velocities but also the angular accelerations equal at that instant in the two systems. Thus, if  $\omega_1, \omega_2, \omega_3$  be the angular velocities of the body about its principal axes, the equations just obtained take the form (due to Euler)

$$A\dot{\omega}_1 + (C - B)\omega_2\omega_3 = L,$$

$$B\dot{\omega}_2 + (A - C)\omega_3\omega_1 = M,$$

$$C\dot{\omega}_3 + (B - A)\omega_1\omega_2 = N.$$

When  $\omega_1, \omega_2, \omega_3$  are found, in any particular case, from these equations, the actual orientation of the body at any time can be calculated from them by the kinematical processes of § 81. The position in space of the point of the body which has been hitherto treated as fixed is to be calculated separately by the processes already explained for kinetics of a particle, and thus the motion of the body is completely determined—in the sense that the difficulties of the further steps are of a purely mathematical nature.

**Rigid body under no forces.** When the forces applied to the body have a single resultant, which either vanishes or passes through the origin, the right-hand terms disappear from Euler's equations. Multiply the equations by  $\omega_1, \omega_2, \omega_3$  respectively, and add. We thus obtain

$$A\omega_1\dot{\omega}_1 + B\omega_2\dot{\omega}_2 + C\omega_3\dot{\omega}_3 = 0,$$

whence  $A\omega_1^2 + B\omega_2^2 + C\omega_3^2 = 2T$  . . . . . (1),

—the statement that the kinetic energy is constant. Again, multiply by  $A\omega_1, B\omega_2, C\omega_3$  respectively, and add. Then we have

$$A^2\omega_1\dot{\omega}_1 + B^2\omega_2\dot{\omega}_2 + C^2\omega_3\dot{\omega}_3 = 0,$$

whence  $A^2\omega_1^2 + B^2\omega_2^2 + C^2\omega_3^2 = D^2$  . . . . . (2),

expressing the constancy of *amount* of moment of momentum.

But if, in these equations, we now choose to regard  $\omega_1, \omega_2, \omega_3$  as the coordinates, parallel to the principal axes, of the extremity of a line which represents, in magnitude and direction, the instantaneous axis, we see that that axis is a central vector of each of the ellipsoids (1) and (2). Hence the instantaneous axis describes, relatively to the body, a cone of the second order. Since  $T$  and  $D$  are the only arbitrary coefficients in the equations, all the ellipsoids (1) or (2) are similar and similarly situated. The curve of intersection of (1) and (2) projected on the plane of the axes  $A$  and  $B$  has the equation

$$A(C - A)\omega_1^2 + B(C - B)\omega_2^2 = 2TC - D^2.$$

This represents an ellipse if the terms on the left have the same sign, *i.e.*, if  $C$  is either greater or less than each of  $A$  and  $B$ . Hence, if the body be originally rotating about an axis nearly coinciding either with the axis of greatest or that of least moment of inertia, it will continue to do so. These two cases are exemplified respectively by a quoit and by an elongated rifle bullet,—at least in so far as the resistance of the air does not interfere with their motion. But if the body be originally rotating about an axis nearly coinciding with the axis of intermediate moment of inertia, the curve indicated by the equation above is an hyperbola or a pair of straight lines through the origin; and the instantaneous axis travels, in general, far away from its first position in the body. We will henceforth look on  $A, B, C$  as in descending order of magnitude. It is obvious from the mode in which they are formed that  $A = B + C$  only when the body is a plate. Hence, generally, any two of  $A, B, C$  are together greater than the third. Also by multiplying (1) by  $A$ , and comparing it term by term with (2), we see that  $2AT > D^2$ ; similarly  $2CT < D^2$ .

To complete the examination of the immediate results of Euler's equations in this case, let us find how the length of the instantaneous axis, considered as a common vector-radius of the ellipsoids (1) and (2), depends on the time.

Let  $\Omega^2 = \omega_1^2 + \omega_2^2 + \omega_3^2$  . . . . . (3);

$$\Omega\dot{\Omega} = \omega_1\dot{\omega}_1 + \omega_2\dot{\omega}_2 + \omega_3\dot{\omega}_3$$

$$= -\left(\frac{C-B}{A} + \frac{A-C}{B} + \frac{B-A}{C}\right)\omega_1\omega_2\omega_3 = -\frac{\Delta}{ABC}\omega_1\omega_2\omega_3,$$

where  $\Delta$  is the determinant

$$\begin{vmatrix} 1 & 1 & 1 \\ A & B & C \\ A^2 & B^2 & C^2 \end{vmatrix} = -(C-B)(B-A)(A-C).$$

Now (1), (2), (3) are linear equations in  $\omega_1^2, \omega_2^2, \omega_3^2$ , and from them we have three equations like

$$\begin{aligned} \Delta\omega_1^2 &= BC(C-B)\Omega^2 + 2T(B^2 - C^2) + D^2(C-B) \\ &= BC(C-B)\{\Omega^2 - \alpha\}, \end{aligned}$$

where

$$\alpha = \frac{2T(B+C) - D^2}{BC}$$

is, by the remark above, essentially positive. Hence

$$\begin{aligned} \Delta^2\omega_1^2\omega_2^2\omega_3^2 &= A^2B^2C^2(C-B)(B-A)(A-C)(\Omega^2 - \alpha)(\Omega^2 - \beta)(\Omega^2 - \gamma) \\ &= A^2B^2C^2\Delta(\alpha - \Omega^2)(\beta - \Omega^2)(\gamma - \Omega^2). \end{aligned}$$

Thus

$$\Omega\dot{\Omega} = \sqrt{(\alpha - \Omega^2)(\beta - \Omega^2)(\gamma - \Omega^2)};$$

whence  $\Omega^2$  is at once found by elliptic functions.  $\Omega$  known, we have  $\omega_1, \omega_2, \omega_3$ , and then by the method of § 81 we have the complete analytical determination of the position of the body in terms of the time.

§ 255. Such a solution, however, fails to give so clear a Poinso't's conception of the nature of the motion as is afforded by rolling the very elegant geometrical representation discovered by ellipsoid. Poinso't. We may arrive at it by considering the tangent plane to (1) at the extremity of the radius  $\Omega$ . If  $x, y, z$  be the current coordinates of that plane, its equation is

$$A\omega_1(\omega_1 - x) + B\omega_2(\omega_2 - y) + C\omega_3(\omega_3 - z) = 0,$$

so that the perpendicular from the origin upon it is equal, by (2), to  $2T/D$ , a constant. The direction cosines of this perpendicular are proportional to  $A\omega_1, B\omega_2, C\omega_3$ , the component moments of momentum. Hence it is the axis of resultant moment of momentum, and is therefore (§ 166) fixed in direction in space. The tangent plane to (1) at the extremity of the instantaneous axis is therefore a fixed plane, and the ellipsoid (1) rolls upon it as if it were perfectly rough. From this we can of course find the equation of the curve of contact with the plane, and thence that of the cone, fixed in space, on which the cone of instantaneous axes in the body rolls, as in § 75. The latter cone is of course given by the intersection of (1) and (2).

To complete this beautiful representation of the motion, all that Sylvester's necessary is a method of measuring time, something to show the rate of rolling of the ellipsoid on the fixed plane. Many constructions have been given for this purpose, such as Poinso't's "rolling and sliding cone," &c., but none can compare in elegance with that Poinso't's invented by Sylvester. We can only sketch a particular case—sufficient, however, to completely solve the question.

Writing  $l, m, n$  for the direction cosines of the fixed line referred to the principal axes, we have

$$l = A\omega_1/D, \quad m = B\omega_2/D, \quad n = C\omega_3/D \quad \dots \dots \dots (4).$$

Our equations (1) and (2) may now be written

$$l^2/A + m^2/B + n^2/C = 2T/D^2 \quad \dots \dots \dots (1),$$

$$l^2 + m^2 + n^2 = 1 \quad \dots \dots \dots (2).$$

Introducing a factor  $p$ , of dimensions the same as  $1/A$ , we have from these a third equation

$$l^2(1/A + p) + m^2(1/B + p) + n^2(1/C + p) = 2T/D^2 + p \quad \dots \dots \dots (5).$$

Now consider an ellipsoid

$$\frac{x^2}{1/A + p} + \frac{y^2}{1/B + p} + \frac{z^2}{1/C + p} = E \quad \dots \dots \dots (6),$$

which is similar, and similarly situated, to one of the ellipsoids confocal with (1) of § 254. Draw to it a tangent plane perpendicular to the line  $OL$ , whose direction cosines are (4). We obtain for the determination of the point of contact  $Q$  three equations of the form

$$l = \frac{x}{S(1/A + p)}, \quad m = \frac{y}{S(1/B + p)}, \quad n = \frac{z}{S(1/C + p)} \quad \dots \dots \dots (7),$$

where

$$S^2 = \frac{x^2}{(1/A + p)^2} + \frac{y^2}{(1/B + p)^2} + \frac{z^2}{(1/C + p)^2}.$$

Here  $x, y, z$  are the coordinates of  $Q$ , and the distance of the tangent plane from the origin is  $E/S$ .

Now (6) gives at once by means of (7)

$$S^2[l^2(1/A + p) + m^2(1/B + p) + n^2(1/C + p)] = E;$$

whence, by (5),

$$S^2 = \frac{E}{2T/D^2 + p}.$$

This is constant, and therefore the new tangent plane is fixed in space.

Let us now find the angular velocity about the fixed line OL of this plane's point of contact Q with the ellipsoid (6).

The direction cosines of the instantaneous axis OP are as  $v_1, \omega_2, \omega_3$ . Those of OQ are as  $x, y, z$ .

And we have obviously by (4) and (7)

$$\begin{vmatrix} \omega_1 & \omega_2 & \omega_3 \\ x & y & z \\ A\omega_1 & B\omega_2 & C\omega_3 \end{vmatrix} = 0.$$

Hence the line OQ lies in the plane containing the instantaneous axis OP and the fixed line OL. The motion of ellipsoid (6) is therefore one of combined sliding and rolling along the new tangent plane. To find the sliding, we must find the angular velocity of Q about the line OL. It is to that about OP, which is  $\Omega$ , in the ratio of the sines of the angles POQ and QOL.

$$\text{But} \quad \sin^2 \text{POQ} = 1 - \frac{(\omega_1 x + \omega_2 y + \omega_3 z)^2}{(x^2 + y^2 + z^2)\Omega^2},$$

$$\text{and} \quad \sin^2 \text{QOL} = 1 - \frac{(A\omega_1 x + B\omega_2 y + C\omega_3 z)^2}{(x^2 + y^2 + z^2)D^2}.$$

By means of the equations (1) and (7) above we find easily

$$\frac{\sin^2 \text{POQ}}{\sin^2 \text{QOL}} = \frac{D^2 p^2}{\Omega^2}.$$

Hence the angular velocity of Q about OL is  $Dp$ , a constant. Now suppose the plane on which the ellipsoid (6) rolls and slides to become perfectly rough, and to be capable of rotating round OL as an axis, there will no longer be sliding of Q, but the plane will be made to rotate with the constant angular velocity  $Dp$ . Thus the time of any portion of the motion of the body will be measured out by the angle of forced rotation of this plane.

**Quoit.** § 256. As a simple example, let us take the case of a quoit, in which A, the moment of inertia about the axis of figure, is greater than either of the equal quantities B and C, which may be referred to any two perpendicular lines in the plane of the quoit. The equations become

$$\begin{aligned} A\dot{\omega}_1 &= 0, \text{ so that } \omega_1 \text{ is constant,} \\ B\dot{\omega}_2 + (A-B)\omega_3\omega_1 &= 0, \\ B\dot{\omega}_3 + (B-A)\omega_1\omega_2 &= 0. \end{aligned}$$

Put for a moment  $\frac{A-B}{B}\omega_1 = n$ , then we have

$$\dot{\omega}_2 + n\omega_3 = 0, \quad \dot{\omega}_3 - n\omega_2 = 0.$$

These give by eliminating  $\omega_3$

$$\ddot{\omega}_2 + n^2\omega_2 = 0.$$

Hence

$$\begin{aligned} \omega_2 &= P \cos(nt + Q), \\ \omega_3 &= -n^{-1}\dot{\omega}_2 = P \sin(nt + Q). \end{aligned}$$

The resultant of these is an angular velocity P, about an axis in the plane of the axes of B and C, and making an angle  $nt + Q$  with the axis of B. Hence the instantaneous axis describes in the body a right cone whose axis is that of figure; it moves round it in the same direction as that in which the body is rotating, and with angular velocity  $n$ . The fixed cone in space is also, obviously, a right cone and the other rolls on it *externally*.

**Cylinder.** If instead of a quoit the body be a long stick or cylinder, we have  $A=B>C$ , and the equations become

$$\begin{aligned} A\dot{\omega}_1 + (C-A)\omega_3\omega_2 &= 0, \\ A\dot{\omega}_2 + (A-C)\omega_3\omega_1 &= 0, \\ C\dot{\omega}_3 &= 0. \end{aligned}$$

The last gives  $\omega_3 = \text{constant}$ , and, if

$$n = \frac{A-C}{A}\omega_3,$$

the first two equations are

$$\dot{\omega}_1 - n\omega_2 = 0, \quad \dot{\omega}_2 + n\omega_1 = 0.$$

Thus

$$\ddot{\omega}_1 + n^2\omega_1 = 0, \quad \omega_1 = P \cos(nt + Q),$$

and

$$\omega_2 = -P \sin(nt + Q).$$

This indicates a rotation of the axis of constant angular velocity P in the negative direction. Everything else is as before, but the cone fixed in the body rolls on the *inside* of that fixed in space.

§ 257. Next let us take the case of a pendulum bob, supported by a flexible but untwistable wire, and containing a gyroscope whose axis is in the direction of the length of the pendulum. Here we may use, for variety, Lagrange's equations. For simplicity we suppose the centres of inertia of the bob and gyroscope to lie in the axis, and the bob to be symmetrical about the direction of the length of the pendulum.

Gyroscopic pendulum.

Let the moment of inertia of the whole about the axis of symmetry be A when the gyroscope is supposed to be prevented from turning relatively to the bob, and let the other two principal moments about the point of suspension be B. Let that of the gyroscope about its axis be C. Then, if  $\theta$  be the inclination to the vertical,  $\phi$  the azimuth of the pendulum, and  $\psi$  a quantity denoting the position of the gyroscope with reference to a definite plane in the bob passing through its axis, we easily find

$$2T = A(1 - \cos\theta)^2\dot{\phi}^2 + B(\dot{\theta}^2 + \sin^2\theta\dot{\phi}^2) + C[\dot{\psi} - (1 - \cos\theta)\dot{\phi}]^2,$$

$$V = Mgl(1 - \cos\theta) = V_0(1 - \cos\theta), \text{ suppose,}$$

where M is the whole mass, and  $l$  the distance from the point of suspension to the centre of inertia of the whole.

The general treatment of this complex problem cannot be attempted here. We may, however, easily obtain useful and characteristic results in some special simple cases, which will enable us to form a general idea of the nature of the motion.

Thus, suppose if possible  $\theta$  to be constant. This is the *Conical Gyroscopic Pendulum*. We easily find the equations

$$\begin{aligned} \dot{\psi} - (1 - \cos\theta)\dot{\phi} &= \Omega = \text{const.} \\ (A(1 - \cos\theta) + B\cos\theta)\dot{\phi}^2 - C\dot{\phi} &= V_0. \end{aligned}$$

gyroscopic pendulum.

For any assigned values of  $\Omega$  and  $\theta$ , this shows what will be the corresponding value of  $\dot{\phi}$ . But it also shows that if we change simultaneously the signs only of  $\Omega$  and  $\dot{\phi}$ , the value of  $\theta$  is unaltered. Thus, reversal of the direction of rotation of the gyroscope involves reversal of the direction of motion of the bob, if the time of rotation is to be unaltered. But to any assigned values of  $\theta$  and  $\Omega$  two values of  $\dot{\phi}$  correspond. As  $\theta$  cannot, in the case considered, exceed  $\frac{\pi}{2}$ , the multiplier of  $\dot{\phi}^2$  is essentially positive. So is  $V_0 = Mgl$ . Hence the values of  $\dot{\phi}$  are real; and one is positive, the other negative. Thus the pendulum, with any rate of rotation of the gyroscope, may be made to move in any horizontal circle; but the angular velocity will be greater when it is in the same sense as that of the rotation of the gyroscope than when it is in the opposite sense. When  $\theta$  is so small that  $\theta^2$  may be neglected, we have

$$B\dot{\phi}^2 - C\dot{\phi} = V_0,$$

or

$$2B\dot{\phi} = C\Omega \pm \sqrt{4BV_0 + C^2\Omega^2}.$$

To give a numerical example, let the mass of the gyroscope be  $\frac{n-1}{n}M$ ; let  $B = Ml^2$ ,  $C = \frac{n-1}{n}M\frac{l^2}{c^2}$ , then

$$2\dot{\phi} = \frac{(n-1)\Omega}{nc^2} \pm \sqrt{4\frac{g}{l} + \left(\frac{n-1}{nc^2}\right)^2\Omega^2}.$$

If  $n=5$ ,  $c=10$ ,  $g=10l$  (which are fair approximations to the dimensions of the ordinary form of the instrument),

$$\dot{\phi} = \frac{2\Omega}{500} \pm \sqrt{10 + \frac{4}{(500)^2}\Omega^2}.$$

Suppose the gyroscope to revolve 100 times per second, then  $\Omega = 200\pi$  practically, and

$$\begin{aligned} \dot{\phi} &= \frac{2}{5}\pi \pm \sqrt{10 + \frac{4}{25}\pi^2} = 2.513 \pm 4.039 \\ &= 6.552 \text{ or } -1.526. \end{aligned}$$

The angular velocity, when the gyroscope is not rotating, would be that of the corresponding conical pendulum,

$$\sqrt{gl} = \pm 3.162;$$

so that in this case the gyroscopic pendulum would rotate about twice as fast, or only about half as fast, as the ordinary conical pendulum, according as it rotated with or against the gyroscope.

If we had taken  $\Omega = 10\pi$  we should have found

$$\dot{\phi} = 3.29 \text{ or } -3.04, \text{ nearly.}$$

Thus the slower the gyroscope rotates the slower is the conical pendulum motion in the same direction, and the quicker that in the opposite direction.

#### STATICS OF A CHAIN OR PERFECTLY FLEXIBLE CORD.

§ 258. AXIOM.—When a body or system is in equilibrium under the action of any forces, additional constraints will not disturb the equilibrium. Compare § 193.

This principle is of very great use in forming the fundamental equations of fluid equilibrium, and thence those of motion. And we find it of advantage, as will be presently seen, in reducing to elementary geometry the problem of the equilibrium of a chain, or perfectly flexible cord.

We may treat this problem, called that of a "catenary," Catenary. by any one of the following methods:—(1) by investigating, as a question of statics of a particle, the conditions of equilibrium of a single link; (2) by imagining a finite portion of the chain to become rigid in its

equilibrium form,—assuming, by the axiom above, that it will remain in equilibrium, and then treating the question by the methods employed for a rigid body; (3) by employing the energy test of equilibrium as in § 198.

§ 259. We exemplify each of these methods in the specially important case of the ordinary catenary.

*Common catenary.* A uniform chain hangs between two fixed points, find the tension at any point and the curve in which the chain hangs.

*First Method.*—Let  $\mu$  be the mass of unit length of the chain;  $T$  the tension at the point  $x, y, z$ ;  $s$  the length of the chain to  $x, y, z$  from some assigned point; and let the axis of  $y$  be taken vertically. Then we have for the equilibrium of the element  $\delta s$ , considered as a material particle,

$$\begin{aligned} T \frac{dx}{ds} - \left( T \frac{dx}{ds} + \frac{d}{ds} \left( T \frac{dx}{ds} \right) \delta s \right) &= 0, \\ T \frac{dy}{ds} + \mu g - \left( T \frac{dy}{ds} + \frac{d}{ds} \left( T \frac{dy}{ds} \right) \delta s \right) &= 0, \\ T \frac{dz}{ds} - \left( T \frac{dz}{ds} + \frac{d}{ds} \left( T \frac{dz}{ds} \right) \delta s \right) &= 0. \end{aligned}$$

Omitting the terms which cancel one another, and dividing by  $\delta s$ , these become

$$\frac{d}{ds} \left( T \frac{dx}{ds} \right) = 0, \quad \frac{d}{ds} \left( T \frac{dy}{ds} \right) = \mu g, \quad \frac{d}{ds} \left( T \frac{dz}{ds} \right) = 0.$$

From the first and third it follows that  $dx/ds$  is constant, i.e., the chain hangs in a vertical plane. We may take it as that of  $xy$ , and the equations are reduced to the first two.

The first gives

$$T \frac{dx}{ds} = T_0,$$

showing that the horizontal component of the tension is constant throughout the whole length of the chain. Substituting for  $T$  in the second, it becomes

$$\frac{d}{ds} \left( \frac{dy}{dx} \right) = \frac{\mu g}{T_0}.$$

The quantity on the right is evidently of  $[L^{-1}]$  dimensions, because that on the left is so; and thus we may write

$$\frac{\mu g}{T_0} = \frac{1}{a}, \quad \text{or} \quad T_0 = \mu g a.$$

Hence  $a$  is the length of a portion of the chain whose weight is equal to the constant horizontal component of the tension.

The equation now becomes

$$\frac{d^2 y}{dx^2} = \frac{1}{a} \frac{ds}{dx} = \frac{1}{a} \sqrt{1 + \left( \frac{dy}{dx} \right)^2}.$$

Integrating, we have

$$\frac{dy}{dx} + \sqrt{1 + \left( \frac{dy}{dx} \right)^2} = C e^{\frac{x}{a}}.$$

If we now assume that the axis of  $y$  passes through the point at which the chain is horizontal, we have at that point  $x=0, \frac{dy}{dx}=0$ , and therefore  $C=1$ . Thus

$$\sqrt{1 + \left( \frac{dy}{dx} \right)^2} + \frac{dy}{dx} = e^{\frac{x}{a}}.$$

Taking the reciprocal of each side, we have

$$\sqrt{1 + \left( \frac{dy}{dx} \right)^2} - \frac{dy}{dx} = e^{-\frac{x}{a}}.$$

Subtracting,

$$2 \frac{dy}{dx} = e^{\frac{x}{a}} - e^{-\frac{x}{a}},$$

or

$$2 \frac{y}{a} = e^{\frac{x}{a}} + e^{-\frac{x}{a}};$$

no constant being added if we assume the axis of  $x$  so that  $y=a, x=0$  together. This is the equation of the curve required.

If we take the sum, instead of the difference, of the above equations, we find

$$2 \frac{ds}{dx} = e^{\frac{x}{a}} + e^{-\frac{x}{a}};$$

so that

$$\frac{2s}{a} = e^{\frac{x}{a}} - e^{-\frac{x}{a}},$$

$s$  being measured from the axis of  $y$ .

But the tension at  $x, y$  is, as above,

$$T = T_0 \frac{ds}{dx} = T_0 \frac{y}{a} = \mu g y.$$

Hence the tension at any point of the chain is equal to the weight of a length of the chain equal to the ordinate at that point.

Thus if a chain of finite length be laid over two smooth parallel rails, its ends, when the whole is equilibrium, will be in the horizontal line corresponding to the axis of  $x$  in the above investigation, the middle part of the chain forming part of the catenary. When a given length  $2l$  of chain rests in equilibrium on two smooth parallel rails at the same level, we have therefore  $s+y=l$ , while  $x=b$ , the half distance between the rails.

By the above expressions for  $y$  and  $s$  in terms of  $x$ , this leads to the equation

$$a e^{\frac{b}{a}} = l,$$

which determines  $a$  when  $b$  and  $l$  are given. From this equation, as the minimum value of the left-hand side occurs when  $a=b$ , we see that the least length of chain for which equilibrium is possible under the conditions is equal to  $e$  times the distance between the rails.

§ 260. *Second Method.*—The chain being in equilibrium, suppose any finite arc of it, as  $PQ$  (fig. 64), to become rigid. The forces acting on  $PQ$  are three—the tensions  $T_1$  and  $T_2$  at its ends, and its weight  $W$  acting at its centre of inertia. But three forces in equilibrium are in one plane (§ 221). Hence the curve is in one vertical plane. Also, as the two tensions are not parallel to one another, the lines of action of all three forces meet in one point. Hence there is no couple, and the conditions are simply

$$\begin{aligned} T_2 \cos \theta_2 - T_1 \cos \theta_1 &= 0, \\ T_2 \sin \theta_2 - T_1 \sin \theta_1 - W &= 0; \end{aligned}$$

where  $\theta_1, \theta_2$  are the inclinations to the horizon of the tangents at the ends of the portion solidified. The first asserts that the horizontal part of the tension is the same at  $P$  and  $Q$ , i.e., all through the chain. The second asserts that the difference of the vertical parts of the tensions at any two points is equal to the weight of the part of the chain between them. By proper mathematical methods these data lead to the results already obtained. In fact the equations we have just obtained are the first integrals of the equations in § 259.

§ 261. *Third Method.*—The potential energy of the chain is

$$\mu g \int y \frac{ds}{dx} dx,$$

with the sole condition

$$\int \frac{ds}{dx} dx = \text{constant},$$

the limits of integration being fixed, and the same for each expression. Hence, by the rules of the calculus of variations, we have the same equations as before.

§ 262. Still supposing gravity to be the only applied force, there are many forms of important questions which can be solved by either chain of these methods. We will take some simple, but varied, examples. Find how the mass of unit length of a chain must vary from point to point so that the catenary may be an assigned plane curve.

We have, as before,

$$\frac{d}{ds} \left( T \frac{dx}{ds} \right) = 0;$$

but our second equation is now

$$\frac{d}{ds} \left( T \frac{dy}{ds} \right) = \mu g,$$

where  $\mu$  is an unknown function of  $s$ . The third equation, being of the same form as the first, shows that the curve is in a vertical plane, and is thenceforth unnecessary.

Fig. 64.

As before, we have

$$T \frac{dx}{ds} = T_0,$$

and

$$\frac{d}{ds} \left( T \frac{dy}{dx} \right) = \frac{\mu g}{T_0}.$$

Now, from the assigned equation of the catenary, the left-hand member can be expressed as a function of  $s$ , and thus we have the solution of the problem. For example, suppose the chain is to hang in an arc of an assigned circle. Referred to the lowest point of the circle, the equation is

$$x^2 = 2ay - y^2,$$

where  $a$  is the radius. From this we have

$$\frac{dy}{dx} = \frac{x}{a-y} = \tan \frac{s}{a},$$

so that

$$\mu = \frac{T_0}{ag} \sec^2 \frac{s}{a}.$$

The tension at the lowest point is thus equal to the weight of a piece of chain like that at the vertex, and of length equal to the radius of the circle; the mass per unit length becomes infinite at the end of a horizontal diameter.

**Suspension bridge.** Next find the form of the chain when the mass of any arc is proportional to its horizontal projection. This is a rough approximation to the case of a suspension bridge where the roadway is uniform, and much more massive than the chains, to which it is attached throughout by vertical ties. The equations are as before, but the additional condition takes the form

$$\mu \frac{ds}{dx} = \mu_0, \text{ a constant.}$$

This gives

$$\frac{d^2y}{dx^2} = \frac{\mu_0 g}{T_0},$$

and the chain forms a parabola whose vertex is downwards, and whose axis is vertical.

**Catenary of uniform strength.** As a final example, we have what is called the *catenary of uniform strength*; that is, the form in which a chain hangs when the tension at every point is proportional to the breaking stress at that point. Here we suppose the strength to be proportional to the section, i.e., to the mass per unit length. This gives the condition

$$T = e\mu.$$

Hence

$$\frac{d}{ds} \left( T \frac{dy}{dx} \right) = \frac{g}{eT_0} T = \frac{g}{e} \frac{ds}{dx},$$

or

$$\frac{d^2y}{dx^2} = \frac{1}{a} \left( \frac{ds}{dx} \right)^2 = \frac{1}{a} \left( 1 + \left( \frac{dy}{dx} \right)^2 \right),$$

where  $a = e/g$ .

This gives

$$\frac{dy}{dx} = \tan \left( \frac{x}{a} + C \right);$$

and the complete integral may be written, by proper selection of origin, in the final form

$$y = a \sec^2 \frac{x}{a}.$$

**Limit of span.** This curve has obviously two vertical asymptotes distant  $\pm \frac{1}{2}\pi a$  from the axis of  $y$ . The quantity  $a$  is directly as the tenacity of the material; and thus we see that there is a limit (even in this simplest case) to the span of a chain, however strong, formed of any known kind of matter.

It is a very curious fact that, if we write the equation of this catenary in terms of the arc and the radius of curvature, it becomes identical with that of the common catenary in terms of Cartesian coordinates, horizontal and vertical. For we see at once that

$$\frac{ds}{dx} = \sec \frac{x}{a},$$

so that

$$\frac{s}{a} = \sqrt{\left( 1 + \sin^2 \frac{x}{a} \right) / \left( 1 - \sin^2 \frac{x}{a} \right)};$$

while by the previous equations

$$\frac{1}{\rho} = \frac{\frac{d^2y}{dx^2}}{\left( \frac{ds}{dx} \right)^3} = \frac{1}{a} \frac{ds}{dx} = \frac{\cos \frac{x}{a}}{a}.$$

Thus finally,

$$\frac{2\rho}{a} = \frac{s}{a} + \frac{s}{a}. \text{ Compare } \S 259.$$

§ 263. When the chain is not uniform, and when it is subject to Catenary the action of other forces than, or besides, gravity, the equations are general.

$$\frac{d}{ds} \left( T \frac{dx}{ds} \right) = -\mu X, \quad \frac{d}{ds} \left( T \frac{dy}{ds} \right) = -\mu Y, \quad \frac{d}{ds} \left( T \frac{dz}{ds} \right) = -\mu Z,$$

where  $X, Y, Z$  are the component forces on unit mass. These three equations involve the unknown quantities  $T, x, y, z$ , and  $s$  only; for  $\mu$  is supposed to be given in terms of  $s$ . Two relations only among  $x, y$ , and  $z$  are wanted (for  $s$  is known in terms of  $x, y, z$ ); so that the equations are necessary and sufficient to give these relations and the remaining unknown  $T$ .

The first members of these equations consist each of two terms:—

$$\frac{dT}{ds} \text{ multiplied respectively by } \frac{dx}{ds}, \frac{dy}{ds}, \frac{dz}{ds},$$

$$\text{and } \frac{T}{\rho} \text{ multiplied by } \rho \frac{d^2x}{ds^2}, \rho \frac{d^2y}{ds^2}, \rho \frac{d^2z}{ds^2};$$

$\rho$  being the radius of curvature of the chain. Hence (§ 22) we conclude that, so far as the tension alone is concerned, the forces on an elementary unit of length of the chain are  $dT/ds$  in the direction of the tangent, and  $T/\rho$  in the direction of the radius of absolute curvature. These must balance the corresponding components of the external forces on the element. Hence we see that the resultant of the applied forces lies, at every point, in the osculating plane. Thus we have

$$\frac{dT}{ds} = -\mu \left( X \frac{dx}{ds} + Y \frac{dy}{ds} + Z \frac{dz}{ds} \right) = -S,$$

$$\frac{T}{\rho} = -\mu \left( X \rho \frac{d^2x}{ds^2} + Y \rho \frac{d^2y}{ds^2} + Z \rho \frac{d^2z}{ds^2} \right) = -N.$$

Here  $S$  and  $N$  are the tangential and normal components of the applied forces per unit length of the chain.

But when a unit particle moves in a curve, we have always Catenary as path of particle.

$$\frac{dv}{dt} = v \frac{dv}{ds} = S', \text{ and } \frac{v^2}{\rho} = N',$$

where  $S'$  and  $N'$  are the normal and tangential components of the requisite force. If we write these in the form

$$\frac{dv}{ds} = \frac{S'}{v}, \quad \frac{v}{\rho} = \frac{N'}{v},$$

and suppose that the curve in which the particle moves is the same as the catenary above, while the speed at each point has the same numerical value as the tension, we see that we must have

$$\frac{S'}{v} = \frac{S'}{T} = -S, \quad \frac{N'}{v} = \frac{N'}{T} = -N;$$

or

$$S' = -ST, \quad N' = -NT.$$

Thus the catenary will be the free path of the particle provided the force applied at any point is equal to the reverse of the product of that acting on the chain by the numerical value of the tension of the chain at that point.

Conversely, if we take any case of free motion of a particle, a uniform chain will hang in the corresponding orbit under the action of the same forces each reversed, and divided by the numerical value of the speed at the corresponding point of the orbit. Thus we can at once pass from particle kinetics to corresponding cases of catenaries.

In the case of a projectile, the path is a parabola, the force is Parabolic constant and parallel to the axis, and the speed is as the square-root of the distance from the directrix. Hence, that the parabola may be a catenary under gravity, it must be turned vertex downwards; and the mass of the chain per unit length at any point must be inversely as the square root of the distance from the directrix. It is easily found from this that the mass of any arc of the chain must be proportional to the length of its horizontal projection, as in the second problem solved in § 262.

In the case of a planet we have

$$v^2 = \mu (2/r - 1/a).$$

Elliptic catenary.

Hence a chain will hang in an ellipse if it be repelled from one focus by a force varying inversely as the square of the distance, the mass per unit length of the chain being directly as the square root of the distance from that focus and inversely as the square root of the distance from the other. If the chain be uniform, the law of the repulsive force from the first focus must be  $1/\sqrt{r^3}$  instead of  $1/r^2$ , where  $r, r'$  are the distances from the two foci.

§ 264. When a chain or string is stretched over a curved surface, the surface must exert a reaction on it to keep it in its curved form. The preceding investigation has shown that the force normal to a chain per unit length at any point is balanced by  $T/\rho$  per unit of length, which must therefore be the magnitude of the reaction. We

may establish this, however, in a very simple manner, as follows:—

Let AB (fig. 65) be a small portion of the cord, and AC, CB the tangents at its extremities; and let the (small) exterior angle at C be  $\theta$ . Then,  $p$  being the pressure per unit length of the string, we have at once

Fig. 65.

$$p \cdot AB = 2T \sin \frac{1}{2}\theta = T\theta$$

ultimately. But  $AB = \rho\theta$ , so that

$$p = T/\rho.$$

Rope If there be friction, and if the element of the rope be just coiled on about to slip, in consequence of the difference of the rough cylinders. tensions at its ends, we have

$$T' - T = \mu p \cdot AB = \mu T\theta,$$

so that

$$T' = T(1 + \mu\theta).$$

This leads to the formula for the growth of a sum at compound interest at  $\mu$  per cent. payable every instant. Hence for a finite angle  $\alpha$  we have

$$T_\alpha = e^{\mu\alpha} T_0.$$

It is to be remarked here that neither the dimensions nor the form of the curve on which the cord is stretched, provided only it be plane, have any influence on this result, which involves only the coefficient of friction and the angle between the two free portions of the cord.

#### KINETICS OF A CHAIN OR PERFECTLY FLEXIBLE CORD.

§ 265. The equations of motion of a chain, under the action of any finite forces, are at once formed from those of equilibrium by introducing the forces of resistance to acceleration according to Newton's principle. Here we enter on a subject of extreme importance, but also (at least in the majority of cases) of great mathematical difficulty. One valuable result, however, can be obtained by very simple means.

Wave-velocity on stretched cord. A uniformly heavy and perfectly flexible cord, placed in the interior of a smooth tube in the form of any curve, and subject to no external forces, will exert no pressure on the tube if it have everywhere the same tension, and move with a certain definite speed.

For, as in § 264, the statical pressure due to the curvature of the rope is  $T\theta/\sigma$  per unit of length (where  $\sigma$  is the length of the arc AB in that figure) directed inwards to the centre of curvature. Now, the element  $\sigma$ , whose mass is  $m\sigma$  (if  $m$  be the mass per unit of length), is moving in a curve whose curvature is  $\theta/\sigma$ , with speed  $v$  (suppose).

The requisite force is  $\frac{mv^2\theta}{\sigma} = mv^2\theta$ , and for unit of length  $mv^2\theta/\sigma$ . Hence if  $T = mv^2$  the theorem is true. If we suppose a portion of the tube to be straight, and the whole to be moving with speed  $v$  parallel to this line, and against the motion of the cord, we shall have the straight part of the cord reduced to rest, and an undulation, of any, but unvarying, form and dimensions, running along it with linear speed  $\sqrt{T/m}$ .

Suppose the tension of the cord to be equal to the weight of  $W$  pounds, and suppose its length  $l$  feet and its own mass  $w$  pounds. Then  $T = Wg$ ,  $lm = w$ , and the speed of the undulation is  $\sqrt{Wlg/w}$  feet per second.

Reflected wave. 266. As will be shown later, when such an undulation reaches a fixed point of the cord or chain, it is reflected, and runs back along the cord with the same definite speed. But the reflected form differs from the incident form in being turned about in its own plane through two right angles. When the string is fixed at both ends any disturbance runs along it, backwards and forwards, with this speed, and

thus (in a piano or harp) administers periodic shocks to the sounding board, causing it to give out a musical note. The interval between these periodic shocks is of course the time taken by the disturbance in running from end to end of the string. Dividing the length  $l$  of the string by the speed above reckoned, we find for this interval the value

$$\sqrt{wl/Wg} = l \sqrt{m/Wg},$$

the reciprocal of which is the number of impulses per second. It is thus seen to be directly as the square-root of the tension of the string, inversely as the square-root of its mass per unit of length, and also inversely as its length. These are well-known facts in Acoustics. It is to be observed that there is no necessity for limiting the proposition above to a plane curve, though we have treated the question as if it were such. The demonstration applies even to a knot of any form.

267. We will now consider more particularly the vibration of a musical string, whose tension is great and its own mass small.

Forming the equations of motion as above hinted, we have three of the type

$$\frac{d}{ds} \left( T \frac{dx}{ds} \right) = -\mu (X - \ddot{x}).$$

In the special case of a tightly stretched inextensible string, performing very small transverse oscillations, we may greatly simplify these by assuming that no external forces act. This practically means that the weight of the string is negligible in comparison with the tension. If the axis of  $x$  be taken to coincide with the undisturbed position of the string, we have to the second order of small quantities

$$s = x.$$

With this the equation above written becomes

$$\frac{dT}{ds} = 0,$$

or the tension is the same throughout. The second and third equations now become

$$T \frac{d^2y}{dx^2} = \mu \ddot{y}, \quad T \frac{d^2z}{dx^2} = \mu \ddot{z}.$$

The  $y$  and  $z$  disturbances are therefore of the same general character, and perfectly independent of one another. We will therefore confine our attention to one of them. From the equations we see that  $T/\mu$  must be of two linear dimensions, and we will therefore write for it  $a^2$ . As this quantity must also be of two negative dimensions in the sum,  $a$  represents a speed. What speed will be seen immediately.

The equation in  $y$  is now

$$a^2 \frac{d^2y}{dx^2} = \ddot{y};$$

whose integral is known to be

$$y = f(at - x) + F(at + x),$$

where  $f$  and  $F$  are arbitrary functions. As we have already seen (§ 53), the first part of the value of  $y$  expresses a wave running with speed  $a$  along the axis of  $x$  in the positive direction; the second part a wave in the negative direction with the same speed. Thus we see that any small disturbance whatever, of a stretched string, gives rise to two series of waves propagated in opposite directions with equal speeds. Also, as the equation is linear, the sum of any two or more particular integrals is also an integral.

If we suppose one extremity of the string to be fixed at the origin, One end fixed. we have the condition  $x = 0$ ,  $y = 0$ , and therefore

$$0 = f(at) + F(at).$$

As this holds for all values of  $t$ , the function  $F$  is simply the negative of  $f$ , so that

$$y = f(at - x) - f(at + x).$$

To investigate what becomes of a disturbance which runs along the cord to the fixed end, let us suppose that  $f(r)$  (which, by the remark above, may represent any part of a disturbance of the string) is a function which vanishes for all values of  $r$  which do not lie between the positive limits  $p$  and  $q$ , but which for values of  $r$  between these limits takes definite values. Then at time  $t = 0$  we have

$$y = -f(x),$$

for, by hypothesis,  $f(r)$  vanishes for all negative values of  $r$ . This denotes a disturbance of the string originally extending from  $x = p$

to  $x=q$ , which runs up to the origin. After the lapse of any interval greater than  $q/a$  we have

$$y=f(at-x),$$

for  $at+x$  has now become greater than  $q$ . This is a wave of exactly the same form as before, but the sign of the disturbance and the direction of its propagation are both reversed. Every portion of a wave is therefore reflected, with simple reversal of the displacement, as soon as it reaches the fixed end. For we may take the limits  $p$  and  $q$  as close together as we choose.

Now suppose the string to have another fixed point at  $x=l$ . Then we have

$$0=f(at-l)-f(at+l).$$

Thus  $f$  is (§ 67) a periodic function, of period  $2l/a$ , and can therefore be expressed as a series of simple harmonic terms of the full period, half period, one-third period, &c. Hence we may write, the coefficient  $\frac{1}{2}$  being put in for convenience,

$$\begin{aligned} y &= \frac{1}{2} \sum_1^\infty A_m \cos \pi m l^{-1} (at-x) + \frac{1}{2} \sum_1^\infty B_m \sin \pi m l^{-1} (at-x) \\ &\quad - \frac{1}{2} \sum_1^\infty A_m \cos \pi m l^{-1} (at+x) - \frac{1}{2} \sum_1^\infty B_m \sin \pi m l^{-1} (at+x) \\ &= \sum_1^\infty A_m \sin \pi m l^{-1} at \sin \pi m l^{-1} x - \sum_1^\infty B_m \cos \pi m l^{-1} at \sin \pi m l^{-1} x. \end{aligned}$$

This expression contains the complete solution of the problem. To adapt it to any particular case, we must know at some definite time (say  $t=0$ ) the value of  $y$  in terms of  $x$ , i.e., the initial disturbance; also the corresponding value of  $\dot{y}$ . We have then

$$\begin{aligned} y_0 &= - \sum_1^\infty B_m \sin \pi m l^{-1} x, \\ \dot{y}_0 &= \frac{\pi a}{l} \sum_1^\infty m A_m \sin \pi m l^{-1} x. \end{aligned}$$

As  $y_0, \dot{y}_0$  are given in terms of  $x$ , we can find, by the process of § 67, the values of  $A_m$  and  $B_m$ , and thence the required value of  $y$ .

268. As another example, suppose a uniform chain to be suspended by one end, and to make small oscillations in a vertical plane.

We cannot enter here into details; so we simply assume that elementary persistent harmonic solutions are possible, or, what comes to the same thing, that there are *permanent* forms in which the chain can rotate about the vertical from the point of suspension.

If the axis of  $x$  be vertical, the equations of motion are

$$\frac{d}{ds} \left( T \frac{dx}{ds} \right) = -\mu(g-x), \quad \frac{d}{ds} \left( T \frac{dy}{ds} \right) = \mu \dot{y};$$

where  $\mu$  is the mass of unit length of the chain. As the oscillations are supposed to be small, we may neglect the change in the vertical ordinate of any point of the chain, because it must be of the second order of small quantities if the horizontal displacement is of the first order. Hence we may put everywhere  $x$  for  $s$ , and therefore consider  $x$  to be independent of  $t$ . Thus the first equation becomes

$$\frac{dT}{dx} = -\mu g;$$

whence

$$T = \mu g(l-x),$$

where  $l$  is the length of the chain. The second equation then becomes

$$(l-x) \frac{d^2 y}{dx^2} - \frac{dy}{dx} = \frac{1}{g} \ddot{y};$$

or, if we measure  $x$  from the lower end of the chain upwards,

$$x \frac{d^2 y}{dx^2} + \frac{dy}{dx} = \frac{1}{g} \ddot{y}.$$

The complete integral of this equation would be much more general than we require, for it would express every possible small motion of the chain, however apparently irregular. What we seek are the fundamental modes of simple harmonic oscillation, any number of which, as in the case of a musical string, may be superposed. Hence we may write

$$\dot{y} = \eta \sin(n\tau + \alpha),$$

where  $n$  is a numerical quantity as yet undetermined, but which is confined to one or other of a series of definite values;  $\eta$ , on the other hand, is a function of  $x$  only. With this value of  $y$  the equation becomes

$$x \frac{d^2 \eta}{dx^2} + \frac{d\eta}{dx} + \frac{n^2}{g} \eta = 0.$$

By the usual method of undetermined coefficients we easily find the particular integral

$$\eta_0 = A \left( 1 - \frac{n^2 x}{g} + \frac{n^4 x^2}{2g^2} - \frac{n^6 x^3}{2^2 g^3} + \dots \right). \quad (1).$$

This series is obviously convergent for all finite values of  $n^2 x/g$ .

The general integral is of the form

$$\eta = B(\eta_1 + \eta_0 \log x) + A \eta_0;$$

where  $\eta_1$  is a function of  $x$ , finite for all values of  $x$ , but which we

need not determine. For it is clear that, to suit our present purpose, we must put  $B=0$ ; otherwise we should have  $\eta$  infinite at  $x=0$ . Thus (1) is the expression we require under the limitations above imposed.

The quantity  $A$  represents the semi-amplitude of oscillation of the lower extremity of the chain. The condition that the upper end is fixed gives  $\eta_0=0$  for  $x=l$ , i.e.,

$$0 = 1 - \frac{n^2 l}{g} + \frac{n^4 l^2}{2g^2} - \frac{n^6 l^3}{2^2 g^3} + \dots$$

The roots of this equation (which are all real and positive) give the values of  $n$  for the several fundamental modes of vibration.

We have  $\eta_0=0$  for the following values of  $n^2 l/g$ : 1.454, 7.62, 18.74, 34.79, &c.

From these we find for the periods of the various simple disturbances the following multiples of the period of a simple pendulum equal in length to the chain, viz., 0.83, 0.36, 0.23, 0.17, &c. When  $n^2 l/g$  has the least of the above values, the chain is always entirely on one side of the vertical, and the time of a complete oscillation is to that of a simple pendulum of the same length as 5:6 nearly.

269. When a free chain, at rest, has an impulsive tension applied Impul- at one end, the calculation of the consequent impulsive tension at sive different parts of the chain and the velocities generated is very tension. simple.

For, calling the instantaneous speeds along the tangent and along the radius of absolute curvature  $v_s$  and  $v_p$  respectively, we have

$$\delta T = \mu v_s \delta s, \quad T/\rho = \mu v_p,$$

where  $\mu$  is the mass of unit length of chain at  $s$ . It is obvious that there can be no impulsive speed perpendicular to the osculating plane. The kinematical condition is simply that an elementary arc  $\delta s$  is not altered in length. But the tangential increment of speed alone would imply an increase of the length of  $\delta s$  in the ratio  $1 + \frac{dv_s}{v_s} \delta t$ : 1 in time  $\delta t$ . Also the impulsive speed  $v_p$  would imply a diminution of its length in the ratio  $1 - v_p \delta t/\rho$ : 1 by virtually making it an arc of a circle of smaller radius, but subtending the same angle at the centre. Hence, neglecting the square of  $\delta t$  as compared with its first power, we find for the kinematical condition

$$\frac{dv_s}{ds} \cdot \frac{v_p}{\rho} = 0$$

This gives, by eliminating the impulsive velocities,

$$\frac{d}{ds} \left( \frac{1}{\mu} \frac{dT}{ds} \right) - \frac{1}{\mu} \frac{T}{\rho^2} = 0.$$

If the chain be uniform, this becomes

$$\frac{d^2 T}{ds^2} - \frac{T}{\rho^2} = 0.$$

The whole kinetic energy generated in the chain by the impulse is

$$\frac{1}{2} \int \frac{ds}{\mu} \left( \left( \frac{dT}{ds} \right)^2 + \frac{T^2}{\rho^2} \right);$$

and the condition that this shall be a maximum is the differential equation above. This is a particular case of a general theorem due to Sir W. Thomson, viz.:-

*A material system of any kind, given at rest, and subjected to an impulse in any specified direction and of any given magnitude, moves off so as to take the greatest amount of kinetic energy which the specified impulse can give it.*

The direction in which an element of the chain begins to move is inclined to the tangent at an angle  $\phi$  where

$$\tan \phi = \frac{v_p}{v_s} = \frac{T}{\rho \frac{dT}{ds}}.$$

270. It is to be observed that, in such questions as those just Waves of treated, the possibility of an impact's being propagated instan- extension taneously along the whole length of a chain depends upon its of a assumed inextensibility. When a wire (such as that employed for string, a distance-signal on railways) is regarded as *extensible*, there is a definite speed with which a disturbance of the nature of extension is transmitted along it.

Thus, recurring to the equations of § 267, we see that for the motion of a stretched elastic string in the direction of its length we have

$$\frac{dT}{ds} = -\mu(X-x).$$

If there be no applied forces,  $X=0$ . Also, if we use  $x$  instead of  $s$  to characterize a particular point of the string, we must put  $x+\xi$  for  $x$  and  $x$  for  $s$ ,  $\xi$  being a function of  $x$  and  $t$  which denotes at any instant the displacement of that point.

The physical condition is expressed by Hooke's Law in the form

$$E \frac{d\xi}{d\alpha} = T.$$

Hence

$$E \frac{d^2\xi}{d\alpha^2} = \mu\xi.$$

This expresses (as in § 267) the passage of simultaneous waves. They are now waves of condensation and extension, not of transverse displacement. The nature of the interpretation of the equation is of the same general character as before, the speed being  $\sqrt{E/\mu}$ .

#### DYNAMICS OF AN ELASTIC SOLID.

§ 271. This subject, which is a very extensive and difficult one, and in its generality quite unsuitable for discussion here, has already been to some extent treated of under ELASTICITY. We therefore content ourselves with one or two examples, whose treatment is comparatively simple, while their applications are frequent and of considerable practical importance.

§ 272. Even so restricted a problem as that of determining the form assumed by a wire or thin rod of homogeneous isotropic elastic material, under the action of given forces and couples, presents somewhat formidable difficulties unless in its unstrained state the wire be straight and truly cylindrical or prismatic. And, even with these limitations, the problem again becomes formidable if we introduce the consideration of non-isotropic material; while, in any case, if the radius of curvature at each point is not very large in proportion to the thickness of the rod in the plane of bending, the problem is to no appreciable extent simplified by the limitation of form of the body. We will therefore give the comparatively simple case of the mere bending and twist of a homogeneous isotropic wire whose natural form is cylindrical or prismatic, the amounts of these from various sources being so small as to be superposable.

Cylindrical or prismatic wire, originally straight.

Bending. Bending lengthens one set of lines of particles originally parallel to the axis of the wire and shortens others.

Twist. Twist lengthens all but one such line, forming them into helices. The more detailed investigation, which we cannot give here, shows that there is one line of particles (the "elastic central line") which passes through the centre of inertia of each transverse section, and which may be treated (under our present limitations) as rigorously unchanged in length. The mutual molecular action of the parts of the wire on opposite sides of any transverse section may of course be reduced to a force and a couple, and the force may be conveniently treated as passing through the centre of inertia of the section. Also the twist and curvature of the wire near this section obviously depend on the couple and not on the force. For the moment of the couple is in general finite, while that of the force (about any point in the corresponding element of the wire) is infinitesimal.

§ 273. Let any two planes, at right angles to one another, be drawn through the elastic central line before distortion; and let them be cut in lines PR and PS by a transverse section through a point P of the central line. Also let PT be a tangent to that line. Suppose a similar construction to be carried out for every point P of the central line. Then it is clear that the form of the distorted wire will be completely determined if we know the form assumed by the central line, and the positions taken by the lines PR and PS drawn from each point in it. In their new positions P'T', P'R', and P'S' will still form (in consequence of the limitations we have imposed) a rectangular system; and the nature of the distortion will be clearly indicated by the change of position of this rectangular system as it passes from point to point of the distorted central line. The plane of rotation of P'T' is the osculating plane of the bending; its rate of rotation in that plane per unit length of the central line is the amount of bending; and the rate of rotation of the system P'R',

P'S', about P'T', per unit length of the central line, is the rate of twist. Suppose P' to move with unit velocity along the distorted central line, and let  $\rho, \sigma, \tau$  be the angular velocities of the system about P'R', P'S', P'T' respectively, then  $\rho$  represents the curvature (or bending) resolved in the plane S'P'T',  $\sigma$  that in R'P'T', while  $\tau$  represents the twist.

Now, if the elastic forces constitute a conservative system, the amount of work done on an element of the body corresponding to a change of form. It must therefore be expressible in the form

where  $w$  is a function of  $\rho, \sigma, \tau$ ; which must be such that the couples producing the bending are

$$\frac{dw}{d\rho} \text{ and } \frac{dw}{d\sigma},$$

while that producing the twist is

$$\frac{dw}{d\tau}.$$

These again, are functions of  $\rho, \sigma, \tau$ , and they must, on account of the principle of superposition, be linear and homogeneous. For, within the limits to which we have restricted ourselves, the doubling alike of bending and twist must involve the doubling of each of the couples. Thus  $w$  must be a homogeneous function of  $\rho, \sigma, \tau$  of the second degree. Hence we may assume

$$w = \frac{1}{2}(A\rho^2 + B\sigma^2 + C\tau^2 + 2D\rho\sigma + 2E\sigma\tau + 2F\tau\rho),$$

where A, B, C, D, E, F are quantities depending on the form of the section of the wire and the nature of its material at each point. This gives

$$\frac{dw}{d\rho} = A\rho + D\sigma + F\tau, \quad \frac{dw}{d\sigma} = D\rho + B\sigma + E\tau, \quad \frac{dw}{d\tau} = F\rho + E\sigma + C\tau.$$

Hence, when the couples are assigned, the amounts of bending and twist are at once calculated from them. But the expression above is much more general than we require for the limited case we are considering. For, if the only couples applied to a portion of the prism or cylinder considered be in planes perpendicular to its length, twist only will be produced. Thus, for  $\frac{dw}{d\rho} = 0, \frac{dw}{d\sigma} = 0$ , we ought to have also  $\rho = 0, \sigma = 0$ . Hence E and F both vanish and we have simply

$$w = \frac{1}{2}(A\rho^2 + 2D\rho\sigma + B\sigma^2 + C\tau^2).$$

This may be reduced, by properly selecting the planes originally drawn through the elastic central line, to the form

$$w = \frac{1}{2}(A\rho^2 + B\sigma^2 + C\tau^2).$$

Now we see that

$$\frac{dw}{d\rho} = A\rho, \quad \frac{dw}{d\sigma} = B\sigma, \quad \frac{dw}{d\tau} = C\tau.$$

§ 274. In a prismatic or cylindrical wire of homogeneous isotropic material, the elastic central line is thus a torsion axis simply. Equal and opposite couples, applied to the ends of such a wire, in planes perpendicular to its length, produce twist in direct proportion to the moments of the couples. There are two planes perpendicular to one another, and passing through this line, such that, if equal and opposite couples in either of these planes be applied at any parts of the wire, the portion between is bent into a circular arc in that plane. These are the principal planes of flexure. The quantities A and B which, when multiplied by the amount of bending in either of these planes, give the moment of the corresponding couple are called the principal "flexure rigidities" of the wire. When they are equal Flexure (as in the case of a wire of circular, square, equilateral, triangular, &c., section) any plane through the axis is a principal plane of flexure. C is the torsional rigidity of the wire. In general, when the wire is fixed at one end and a couple applied at the other, the wire assumes the form of a circular helix. The exceptions (or rather particular cases) are:—(a) when the plane of the couple contains the elastic central line, and there is mere flexure, without twist; (b) when the plane of the couple is perpendicular to the wire, and there is twist simply.

§ 275. As an example of the preceding theory, take first

Flexure of plank by its own weight.

the case of a uniform plank clamped horizontally at one end, and otherwise unsupported. This is obviously the same as the case of a plank of double the length, supported by a trestle placed under its middle. We assume as before that the radius of curvature is always very large compared with the thickness of the plank.

In all such cases we may at once apply the principle of § 258, and suppose one portion of the plank up to a section P to be fixed in its equilibrium position. The curvature immediately contiguous to P will then be simply proportional to the moment about P of the forces acting on the unfixed portion. Hence at the free end there will be no curvature, and the curvature at points near that end will be of the second order of infinitesimals; i.e., its rate of increase at the end vanishes.

Let  $x$  be the length of the fixed portion,  $l$  the whole length of the plank. Then, as the deflexion  $y$  from the horizontal is always very small, the curvature is expressed (§ 22) by

$$\frac{d^2y}{dx^2},$$

so that we have at once

$$E \frac{d^2y}{dx^2} = -\mu g \int_0^{l-x} x' dx' = -\frac{1}{2} \mu g (l-x)^2,$$

where  $E$  is the "flexural rigidity" of the plank, and  $\mu$  its mass per unit of length.

Successive integrations give

$$E \frac{dy}{dx} = B + \frac{1}{6} \mu g (l-x)^3,$$

and

$$Ey = A - B(l-x) - \frac{1}{24} \mu g (l-x)^4.$$

The terminal conditions are

$$\text{for } x=0, \quad y=0, \quad \frac{dy}{dx}=0;$$

$$\text{and for } x=l, \quad \frac{d^2y}{dx^2}=0, \quad \frac{d^3y}{dx^3}=0.$$

The last two are obviously satisfied.

The two former give

$$B = -\frac{\mu g l^3}{6}, \quad A = Bl + \frac{1}{24} \mu g l^4 = -\frac{1}{24} \mu g l^4.$$

$$\text{Hence} \quad Ey = -\frac{1}{24} \mu g (3l^4 - 4l^3(l-x) + (l-x)^4).$$

Thus the droop of the free extremity ( $x=l$ ) is

$$\frac{\mu g l^4}{8E} = \frac{Wl^3}{8E},$$

where  $W$  is the whole weight.

If the plank had been weightless, but loaded at the free end with a weight  $W$ , our equation would have been

$$E \frac{d^2y}{dx^2} = -W(l-x),$$

and we should have had

$$E \frac{dy}{dx} = B' + \frac{1}{2} W(l-x)^2,$$

$$Ey = A' - B'(l-x) - \frac{1}{6} W(l-x)^3.$$

The terminal conditions at  $x=0$  are as before, so that

$$B' = -\frac{1}{2} Wl^2, \quad A' = -\frac{1}{2} Wl^3 + \frac{1}{6} Wl^3 = -\frac{1}{3} Wl^3,$$

and the droop of the free end is  $\frac{Wl^3}{3E}$ , greater than before in the ratio of 8:3.

If the plank be again looked on as heavy, but its free end be supported on a trestle which is pressed upwards till it acts with a force  $W$ , we find directly

$$E \frac{d^2y}{dx^2} = W(l-x) - \frac{1}{2} \mu g (l-x)^2,$$

$$E \frac{dy}{dx} = B'' - \frac{1}{2} W(l-x)^2 + \frac{1}{6} \mu g (l-x)^3,$$

$$Ey = A'' - B''(l-x) + \frac{1}{6} W(l-x)^3 - \frac{1}{24} \mu g (l-x)^4.$$

The terminal conditions, at  $x=0$ , are still as in the first case, and they give

$$B'' = \frac{1}{2} Wl^2 - \frac{1}{6} \mu g l^3,$$

when the amount by which the free end is raised is

$$\frac{A''}{E} = \left[ \frac{1}{2} Wl^3 - \frac{1}{6} \mu g l^4 \right] / E = \frac{5Wl^3}{24E}.$$

This is obviously the same as the amount of depression of the middle of a plank of length  $2l$  supported by trestles at each end.

§ 276. Hence the droop of the middle of a plank resting on trestles at its ends is to that of the ends when the plank rests on a single trestle at the middle in the ratio of 5:3.

If the equation expressing the curvature in the first or third cases above be twice differentiated, the common result is

$$E \frac{d^4y}{dx^4} = -\mu g.$$

The simplicity of this expression leads us to seek for the most general form. Suppose the plank to be exposed to any system of forces in lines perpendicular to its length and breadth. Then, if any transverse section be made, the stress between the two portions of the plank will consist of forces ( $\pm G$ ) and couples ( $\pm H$ ) in the plane of length and thickness. Let the applied forces be  $N$  per unit of length. Suppose also, as before, that the radius of curvature is very great compared with the thickness. Then the equations of equilibrium of an element are

$$\frac{dG}{dx} + N = 0, \quad \frac{dH}{dx} + G = 0.$$

We have also the condition of bending, viz.,

$$E \times \text{curvature} = E \frac{d^2y}{dx^2} = H.$$

Eliminating  $H$  and  $G$  among these equations, we have

$$E \frac{d^4y}{dx^4} = \frac{d^2H}{dx^2} = -\frac{dG}{dx} = N,$$

which of course includes all the previous particular cases. We may now determine (under the limits imposed) the form of a uniform plank of any length, supported in a nearly horizontal position at different points in its length, and loaded at any assigned points with any weights. The importance of this in practice is obvious.

§ 277. But we may easily take a further step, and investigate the oscillatory motion, so long at least as the acceleration parallel to the length of the plank and its rotation are negligible. For in such a case, if  $\mu$  be the mass per unit of length, the equation of motion is (§ 199)

$$E \frac{d^4y}{dx^4} = N - \mu y.$$

We will consider only the case in which the applied force  $N$  may be neglected. This is practically the case of a uniform wire or flat rectangular spring. Suppose, further, that it is fixed at one end and free at the other, like Wheatstone's "kaleidophone," or like the tongue of a reed organ-pipe.

Then, writing  $n^4$  for the fraction  $\mu/E$ , we have

$$\frac{d^4y}{dx^4} + n^4 y = 0.$$

A particular integral may obviously be found in the form

$$y = \eta \cos(i^2 x / n^2 + \alpha) \dots \dots \dots (1),$$

where  $\eta$  (a function of  $x$ ) and  $i/n$  (a constant number) have to be found;  $\alpha$  is any constant. The substitution of this value of  $y$  leads to

$$\frac{d^4\eta}{dx^4} - i^4 \eta = 0,$$

the complete integral of which is

$$\eta = A e^{ix} + B e^{-ix} + C \cos(ix + D).$$

Now, provided the value of  $i$  be properly determined, the motion represented by (1), with the above value of  $\eta$ , can exist by itself; and the most general motion of which the spring is capable (under the limits imposed) consists of superposition of a number of separate motions of a similar character. Hence this may be treated by itself. Our limiting conditions in the present case are

$$x=0, \quad \eta=0, \quad \frac{d\eta}{dx}=0 \text{ at the fixed end;}$$

$$\text{and} \quad x=l, \quad \frac{d^2\eta}{dx^2}=0, \quad \frac{d^3\eta}{dx^3}=0 \text{ at the free end.}$$

Now, from the value of  $\eta$  above, we have

$$\frac{1}{i} \frac{d\eta}{dx} = A\varepsilon^{ix} - B\varepsilon^{-ix} - C\sin(ix + D),$$

$$\frac{1}{i^2} \frac{d^2\eta}{dx^2} = A\varepsilon^{ix} + B\varepsilon^{-ix} - C\cos(ix + D),$$

$$\frac{1}{i^3} \frac{d^3\eta}{dx^3} = A\varepsilon^{ix} - B\varepsilon^{-ix} + C\sin(ix + D).$$

Hence we have

$$\begin{aligned} 0 &= A + B + C\cos D, \\ 0 &= A - B - C\sin D, \\ 0 &= A\varepsilon^{il} + B\varepsilon^{-il} - C\cos(il + D), \\ 0 &= A\varepsilon^{il} - B\varepsilon^{-il} + C\sin(il + D). \end{aligned}$$

Eliminating  $C$  and  $D$ , we have

$$\begin{aligned} 0 &= A\varepsilon^{il} + B\varepsilon^{-il} + (A + B)\cos il + (A - B)\sin il, \\ 0 &= A\varepsilon^{il} - B\varepsilon^{-il} - (A + B)\sin il + (A - B)\cos il. \end{aligned}$$

Eliminate the ratio  $A/B$ , which is all that these equations furnish, and we have

$$(\varepsilon^{il} + \varepsilon^{-il})\cos il + 2 = 0.$$

From this equation the values of  $i$  must be determined. It is clear that the multiplier of  $\cos il$  is always greater than 2, except in the special case of  $i = 0$ , which we obviously need not consider, as it gives  $y = 0$ , and therefore belongs to the statical problem already considered. Hence  $as$ , to make  $\cos il$  negative,  $il$  must be greater than  $\frac{1}{2}\pi$ ; and, as  $\varepsilon^{\frac{1}{2}\pi} + \varepsilon^{-\frac{1}{2}\pi} = 5$  nearly, it is clear that the excess of the first value of  $il$  over  $\frac{1}{2}\pi$  is somewhere about  $0.3$ . The next value falls short of  $\frac{3}{2}\pi$  by a quantity of the order  $\frac{1}{1000}$ , the next exceeds  $\frac{5}{2}\pi$  by a quantity of the order  $\frac{1}{10000}$ , &c. The required values arrange themselves in two groups, one of either group being taken alternately. The first group involves arcs a little greater than but rapidly approaching to the values of  $(4m+1)\frac{1}{2}\pi$ ; the second consists of arcs a little less than but rapidly approaching to those of  $(4m+3)\frac{1}{2}\pi$ .

Effects of pressure on tubes and spherical shells.

§ 278. Some of the simplest, but at the same time most practically useful, of questions connected with elasticity of solids relate to the changes of form or volume experienced by circular cylindrical tubes or spherical shells exposed to hydrostatic pressure. A steam-boiler, the cylinders and tubes of an hydraulic press, a fowling-piece or cannon and (on a much smaller scale) Ørsted's piezometer, deep-sea thermometers, &c., afford common instances. All that is necessary for attacking such questions is given in §§ 45, 46 of the article ELASTICITY. For it is there shown that, if a homogeneous isotropic elastic solid be subjected to a simple longitudinal stress  $P$ , uniform and in a definite direction throughout its whole substance, the result will be linear extension  $= P\left(\frac{1}{3n} + \frac{1}{9k}\right)$  in the direction of  $P$ , and linear contraction  $= P\left(\frac{1}{6n} - \frac{1}{9k}\right)$  in all directions perpendicular to  $P$ . The quantities  $n$  and  $k$ , as explained in the article referred to, are respectively the "rigidity" and the reciprocal of the "compressibility" of the solid operated on.

Equal pressures within and without piezometer.

§ 279. The case of the piezometer, in which the vessel holding the liquid whose compression is to be measured is exposed both inside and outside to the same hydrostatic pressure, is seen to correspond to three equal stresses in directions at right angles to one another. These directions may be any whatever, and in each of them the linear extension is obviously

$$P \left\{ \left( \frac{1}{3n} + \frac{1}{9k} \right) - 2 \left( \frac{1}{6n} - \frac{1}{9k} \right) \right\} = \frac{P}{3k}.$$

$P$  is negative, as the stress is a pressure. Hence the strain consists in a simple alteration of volume measured by  $P/k$ . Every part of the walls of the vessel, as well as its external bulk, and its interior content, is altered to the same extent.

Cylinder under internal pressure.

§ 280. In the case of a cylinder, when the internal and external pressures are different, it is clear from symmetry that the stresses may be resolved at any point of the walls into three at right angles to one another, the first ( $P_1$ ) parallel to, the second ( $P_2$ ) at right angles to, the axis, and the third ( $P_3$ ) perpendicular to each of the other

two. In a transverse section of the cylinder, the second of these is radial and the third is tangential to a coaxial cylinder passing through the element considered. We suppose the cylinder closed at both ends, and we make the further assumption (quite exact enough for practical applications, and most important from the point of view of simplicity of calculation) that all transverse sections of the cylinder remain, after distortion, transverse sections. This is equivalent to assuming  $P_1$  to be constant throughout the walls of the cylinder. Hence, if there be interior pressure only, the value of this stress must be

$$P_1 = \frac{\text{pressure on end of interior of cylinder}}{\text{area of transverse section of walls of cylinder}} = \frac{\Pi a_0^2}{a_1^2 - a_0^2},$$

where  $\Pi$  is the interior hydrostatic pressure, and  $a_0, a_1$  are the internal and external radii. This stress represents a longitudinal tension of the walls of the cylinder.

Let us consider an element of the cylindrical wall, defined as follows in the unstrained state:—

Draw two transverse sections at distances  $x$  and  $x + \delta x$  from one end, two planes through the axis making an (infinitesimal) angle  $\theta$  with one another, and two cylinders of radii  $r$  and  $r + \delta r$  about the common axis. In the strained state  $\theta$  is unchanged, but  $x$  becomes  $x + \xi$ , and  $r$  becomes  $r + \rho$ . The distance between the transverse sections was  $\delta x$ ; it becomes  $\delta x + \frac{d\xi}{dx} \delta x$ , so that the linear extension parallel to the axis is  $\frac{d\xi}{dx}$ .

The distance between the cylinders was  $\delta r$ ; it becomes  $\delta r + \frac{d\rho}{dr} \delta r$ , so that the radial extension is  $\frac{d\rho}{dr}$ . The breadth of the base of the wedge-shaped element was  $r\theta$ ; it becomes  $(r + \rho)\theta$ , so that the linear extension perpendicular alike to the radial line and to the axis is  $\frac{\rho}{r}$ .

If we now write, for simplicity,

$$e = \frac{1}{3n} + \frac{1}{9k}, \quad f = \frac{1}{6n} - \frac{1}{9k},$$

the three requisite equations between stresses and strains are at once obvious in the form

$$\frac{d\xi}{dx} = eP_1 - fP_2 - fP_3,$$

$$\frac{d\rho}{dr} = -fP_1 + eP_2 - fP_3,$$

$$\frac{\rho}{r} = -fP_1 - fP_2 + eP_3.$$

We have, however, four unknown quantities  $\xi, \rho, P_2$ , and  $P_3$ , so that another equation is required. This must be supplied by one of the statical conditions of equilibrium of the element above defined, when in its strained state. There is obviously equilibrium in the axial direction, and also parallel to the base of the element; but radially we have a case resembling that of an element of a cord as in § 264. Neglecting small quantities of a higher order than those retained, this consideration gives

$$P_3 \delta \theta \delta x \delta r = \frac{d}{dr} (P_2 r \delta \theta \delta x) \delta r, \quad \text{or} \quad P_3 = \frac{d}{dr} (P_2 r).$$

Solving the four equations, and taking account of the boundary conditions

$$P_2 = -\Pi \text{ when } r = a_0, \text{ and } P_2 = 0 \text{ when } r = a_1,$$

we obtain the following values:—

$$\frac{d\xi}{dx} = \Pi \frac{a_0^2}{a_1^2 - a_0^2} (e - 2f),$$

$$\frac{\rho}{r} = \Pi \frac{a_0^2}{a_1^2 - a_0^2} \left[ (e - 2f) + \frac{a_1^2}{r^2} (e + f) \right],$$

$$\frac{d\rho}{dr} = \Pi \frac{a_0^2}{a_1^2 - a_0^2} \left[ (e - 2f) - \frac{a_1^2}{r^2} (e + f) \right];$$

or, reintroducing the values of  $e$  and  $f$ ,

$$\frac{d\xi}{dx} = \frac{\Pi a_0^2}{a_1^2 - a_0^2} \frac{1}{3k},$$

$$\frac{\rho}{r} = \frac{\Pi a_0^2}{a_1^2 - a_0^2} \left( \frac{1}{3k} + \frac{a_1^2}{r^2} \frac{1}{2n} \right),$$

$$\frac{d\rho}{dr} = \frac{\Pi a_0^2}{a_1^2 - a_0^2} \left( \frac{1}{3k} - \frac{a_1^2}{r^2} \frac{1}{2n} \right).$$

§ 281. Thus the nature of the distortion produced in the walls of a cylindrical tube by internal pressure may be described as made up

of a uniform dilatation, whose linear measure in every direction is  $\frac{\Pi a_0^2}{a_1^2 - a_0^2} \frac{1}{3k}$ , combined with a shear in each transverse section, whose measure is  $1 \pm \frac{\Pi a_0^2 a_1^2}{(a_1^2 - a_0^2) r^2} \frac{1}{2n}$ . § 91.

The shorter axis of this shear is radial, and the magnitude of the shear is obviously greater for smaller values of  $r$ . The inner layer of the walls is thus the most distorted. The amount of the distortion is directly as the pressure, and inversely as the area of the section of the walls.

When the walls are very thin the shear is practically the same throughout their thickness. When they are very thick, the shear near the inner surface is nearly  $1 \pm \frac{\Pi}{2n}$ , however fine be the bore.

That near the outer surface is nearly  $1 \pm \frac{a_0^2}{a_1^2} \frac{\Pi}{2n}$ , which vanishes when the bore is very fine. Thus it appears that, if a stout tube bursts by the shear produced by internal pressure, little is gained either by making it of extremely great thickness or by making it of very small bore.

The diagrams A and B in fig. 66 show, necessarily on a greatly exaggerated scale, the nature of the distortion produced at different

Fig. 66:

parts of the wall of the tube. They represent transverse sections of small, originally spherical, elements made by planes at right angles to the axis. The radial diameters are horizontal. A is an element close to the external surface, B an element near the inner surface. The increase per unit volume of the interior of the tube is

$$\frac{\Pi a_0^2}{a_1^2 - a_0^2} \left( \frac{1}{k} + \frac{a_1^2}{a_0^2} \frac{1}{n} \right);$$

so that, if the tube be very thick in comparison with its bore, the increase is nearly  $\Pi/n$ . In flint glass this is approximately about  $\frac{1}{10000}$ , when  $\Pi$  is a ton-weight per square inch.

§ 282. The reader who has followed the above investigation will find no difficulty in obtaining the corresponding results for a cylindrical tube, closed at both ends and exposed to external pressure  $\Pi$ , in the form

$$\begin{aligned} \frac{d\xi}{dx} &= -\frac{\Pi a_1^2}{a_1^2 - a_0^2} \frac{1}{3k}, \\ \frac{\rho}{r} &= -\frac{\Pi a_1^2}{a_1^2 - a_0^2} \left( \frac{1}{3k} + \frac{a_0^2}{r^2} \frac{1}{2n} \right), \\ \frac{d\rho}{dr} &= -\frac{\Pi a_1^2}{a_1^2 - a_0^2} \left( \frac{1}{3k} - \frac{a_0^2}{r^2} \frac{1}{2n} \right). \end{aligned}$$

The only comments we need make are (1) that the signs of these distortions are now negative; (2) that they are (so far as change of volume is concerned) greater than for the internal pressure, as  $a_1^2$  has taken the place of  $a_0^2$  as a factor in each term involving  $k$ ; (3) that the terms involving the rigidity are, except as regards sign, unchanged.

The change of volume of every part of the walls is

$$-\frac{\Pi a_1^2}{a_1^2 - a_0^2} \frac{1}{k},$$

and the change of volume of the interior is

$$-\frac{\Pi a_1^2}{a_1^2 - a_0^2} \left( \frac{1}{k} + \frac{1}{n} \right).$$

The numerical value of the factor  $\Pi \left( \frac{1}{k} + \frac{1}{n} \right)$  is about  $\frac{1}{10000}$  for flint glass and about  $\frac{1}{1000}$  for steel, when  $\Pi$  is a ton-weight per square inch. There is, however, a peculiarity which (when the walls are thick enough) distinguishes this from the preceding case. For  $k$  is usually considerably greater than  $n$ , so that *a fortiori*  $3k$  is greater than  $2n$ . Hence, in the value of  $d\rho/dr$ , the term in  $n$  is always greater than that in  $k$  so long as the pressure is internal. Thus the radial effect is compression at all parts of the walls. But, when the pressure is external, we may (if the walls be thick enough) find a value of  $r$  for which

$$\frac{1}{3k} = \frac{a_0^2}{r^2} \frac{1}{2n}.$$

In glass, this occurs when  $r = 1.6a_0$  nearly. At this distance from the axis there is no radial change of length; at greater distances there is radial compression, and at smaller radial extension. This is indicated in the diagrams C and D in fig. 66, which like the former are greatly exaggerated. They represent the distortion

of small spherical elements of a thick tube,—the first at the inner wall, the second at the outer surface. As before, these are sections made by a plane perpendicular to the axis of the cylinder.

§ 283. In a spherical shell of internal and external radii  $a_0$  and  $a_1$ , the equations become a little more simple on account of the shell under external pressure.

Using the same notation, so far as it is now applicable, we have

$$\frac{d\rho}{dr} = -2fP_1 + cP_2, \quad \frac{\rho}{r} = (e-f)P_1 - fP_2.$$

The statical equation is

$$2rP_1 = \frac{d}{dr}(r^2P_2).$$

With these we obtain, for external pressure  $\Pi$ , the result

$$\frac{\rho}{r} = -\Pi \frac{a_1^3}{a_1^3 - a_0^3} \left( \frac{1}{3k} + \frac{a_0^3}{r^3} \frac{1}{4n} \right),$$

from which the other equation may be derived by differentiation.

§ 284. The propagation of plane waves in an elastic solid has been discussed in ELASTICITY, and the mechanics of fluids is discussed under HYDROMECHANICS.

### GENERAL CONSIDERATIONS.

§ 285. The preceding view of the subject of Abstract General Dynamics has been based entirely upon Newton's Laws of Motion, which were adopted without discussion, as a complete and perfectly definite foundation; and the terms employed, as well as the mode of treatment in general, have somewhat closely followed Newton's system. The only considerable apparent departure from that system is connected with the development of the idea of energy, and its application to the simplification of many of the methods and results. This also was, as we have seen, really introduced by Newton; but it has been immensely extended since his time both by mathematical and by experimental processes. It is time that we should now return to the laws of motion, and examine more closely, in the light of what we have learned, one or two of the more prominent ideas which they embody. To do so fairly we must go back to Newton's own definitions of the terms which he employs. About many of these, which have already been quoted in §§ 97–113, there is no difference of opinion. But it is otherwise when we come to the definition of "force" (§§ 5, 104).

There can be no doubt that the proper use of the term Force, "force" in modern science is that which is implied in the statement of the first law of motion, as we rendered it in § 1 from Newton's Latin. It is thus seen to be the English equivalent of the term *vis impressa*. Newton uses the word *vis* in other connexions, and with a certain vagueness inevitable at a time when the terminology of science was still only shaping itself; but his idea of "force" was perfectly definite, and when *this* is in his mind the vague word *vis* is (when necessary) always qualified and rendered precise, either by the addition of *impressa* or in some equally unambiguous way. To render *vis* by "force," wherever it stands without the *impressa* or its equivalents, is to introduce a quite gratuitous confusion for which Newton is not responsible. We have only to think of the multitude of terms, such as *vis insita* (inertia), *vis acceleratrix* (acceleration), *vis viva* (kinetic energy), &c., &c., to see that all such complex expressions must be regarded as *wholes*, and that *vis* does not mean "force" in any one of them.

§ 286. Thus in Newton's view *force* is whatever changes (but not "or tends to change") a body's state of rest or of uniform motion in a straight line.

He mentions, as instances, percussion, pressure, and central force.<sup>1</sup> Under the last of these heads he expressly includes magnetic as well as gravitational force. Thus

<sup>1</sup> *Vis centripeta*. It has been already explained that such words as *centripeta* include *impressa*, so that the above rendering of Newton's phrase is the obvious one.

force may have different origins, but it is always one and the same; and it produces, in any body to which it is applied, a change of momentum in its own direction, and in amount proportional to its magnitude and to the time during which it acts.

Equilibrium.

§ 287. Thus, from Newton's point of view, equilibrium is not a balancing of forces, but a balancing of the effects of forces. When a mass rests on a table, gravity produces in it a vertically downward velocity which is continually neutralized by the equal upward velocity produced by the reaction of the table; and these forces, whose origins and places of application are alike so widely different, are (as forces), in every respect except direction, similar and equal. And they are so because they produce, in equal times, equal and opposite quantities of motion.

Origin of the idea of force.

§ 288. The idea of "force" was undoubtedly suggested by the "muscular sense"; and there can be no question as to the vividness of the sensation of effort we experience when we try to lift a heavy weight or to open a massive gate. In this, as in other cases, it is the business of science to find what objective fact corresponds to the subjective data of sensation. It is very difficult to realize the fact, certain as it is, that light (in the sense of *brightness*) is a mere sensation or subjective impression, and has no objective existence. Yet we know that, beside those radiations which give us the sensation of light, there are others, in endless series both higher and lower in their refrangibility, to which our eyes are absolutely blind. And the only difference between these and the former is one of mere wave-length or of period of vibration. Similarly, it is very hard to realize the fact that sound (in the sense of *noise*) is only a sensation; and that outside us there is merely a series of alternate compressions and dilatations of the air, the great majority of which produce no sensible effect upon our ears. Thus because we know that we should seek in vain for brightness or noise in the external world, familiar as our senses have rendered us with these conceptions, we are driven to inquire whether the idea of *force* may not also be a mere suggestion of sense, corresponding (no doubt) to some process going on outside us, but quite as different from the sensation which suggests it as is a periodic shearing of the ether from brightness, or a periodic change of density of air from noise.

Stress.

§ 289. So far, we have treated of force as acting on a body without inquiring whence or why; we have referred to the first and second laws of motion only, and have thus seen only one half of the phenomenon. As soon, however, as we turn to the third law, we find a new light cast on the question. Force is always dual. To *every* action there is *always* an equal and contrary reaction. Thus the weight which we lift or try to lift, and the massive gate which we open or try to open, both as truly exert force upon our hands as we do upon them. This looking to the other side of the account, as it were, puts matters in a very different aspect. "Do you mean to tell me," said a medical man of the old school, "that, if I pull a 'subject' by the hand, it will pull me with an equal and opposite force?" When he was convinced of the truth of this statement, he gave up the objectivity of force at once.

Tension and pressure.

§ 290. The third law, in modern phraseology, is merely this:—

*Every action between two bodies is a stress.*

When we pull one end of a string, the other end being fixed, we produce what is called *tension* in the string. When we push one end of a beam, of which the other end is fixed, we produce what is called *pressure* throughout the beam. Leaving out of account, for the moment, the effects of gravity, this merely amounts to saying that there is stress across every transverse section of the string or beam. But, in the case of the string, the part of the stress which every

portion exerts on the adjoining portion is a *pull*; in the case of the beam it is a *push*. And all this distribution of stress, though exerted across every one of the infinitely numerous cross sections of the string or beam, disappears the moment we let go the end. We can thus, by a touch, call into action at will an infinite number of stresses, and put them out of existence again as easily. This, of itself, is a very strong argument against the supposition that force, in any form, can have objective reality.

§ 291. We must now say a word or two on the question Objective of the objective realities in the physical world. If we inquire carefully into the grounds we have for believing that matter (whatever it may be) has objective existence, we find that by far the most convincing of them is what may be called the "conservation of matter." This means that, do what we will, we cannot alter the mass or quantity of a portion of matter. We may change its form, dimensions, state of aggregation, &c., or (by chemical processes) we may entirely alter its appearance and properties, but its quantity remains unchanged. It is this experimental result which has led, by the aid of the balance, to the immense developments of modern chemistry. If we receive this as evidence of the objective reality of matter, we must allow objective reality to anything else which we find to be conserved *in the same sense* as matter is conserved. Now there is no such thing as negative mass; mass is, in mathematical language, a signless quantity. Hence the conservation of matter does not contemplate the simultaneous production of equal quantities of positive and negative mass, thus leaving the (algebraic) sum unchanged. But this is the nature of conservation of momentum (§ 165) and of moment of momentum. The only other known thing in the physical universe, which is conserved in the same sense as matter is conserved, is energy. Hence we naturally consider energy as the other objective reality in the physical universe, and look to it for information as to the true nature of what we call force.

§ 292. When we do so, the answer is easily obtained, True and in a completely satisfactory form. We give only a very simple instance. When a stone, whose mass is  $M$  and weight  $W$ , has fallen through a space  $h$  towards the earth, it has acquired a speed  $v$ , which (§ 28) is given by the equation

$$\frac{1}{2}Mv^2 = Wh.$$

This is a particular case of the conservation of energy, but the terms in which it is expressed are those suggested by Newton's laws of motion, and are therefore based on the recognition of "force." The first member of the equation represents the kinetic energy acquired; the second the potential energy lost, or the work done by gravity upon the stone during its fall. Both members therefore express real things, having objective existence.

But the "force" (so-called) which is said to have produced the motion, has the value

$$W = \frac{1}{2}Mv^2/h,$$

i.e., it is the *rate per unit of length*, at which potential energy is converted into kinetic energy during the fall. In other words, it is merely an expression for the *space-rate at which energy is transformed*.

§ 293. Another mode of presenting the case will make this still more clear. The average speed with which the stone falls is (§ 28)  $v/2$ . Divide both sides of the equation above by this quantity, remembering that  $2h/v$  is the time of falling, which we call  $t$ . We have thus, as another perfectly legitimate deduction from our premises,

$$W = Mv/t.$$

Here the (so-called) force appears in a new light. It is now the *time-rate at which momentum is generated* in the falling stone.

§ 294. The statements in the last two sections are, in fact, merely particular cases of Newton's two interpretations of action in the third law, which have already been discussed (§§ 165, 167).

Analytically, the whole affair is merely this: if  $s$  be the space described,  $v$  the speed of a particle,

$$\dot{s} = v = \frac{dv}{dt} = \frac{dv}{ds} \cdot \frac{ds}{dt} = v \frac{dv}{ds}.$$

Hence the equation of motion (formed by the second law)

$$ms = m\dot{v} = f,$$

which gives  $f$  as the time-rate of increase of momentum, may be written in the new form

$$mv \frac{dv}{ds} = \frac{d}{ds} (\frac{1}{2} mv^2) = f,$$

giving  $f$  as the space-rate of increase of kinetic energy.

Rate.

§ 295. But a mere *rate*, be it a space-rate or a time-rate, is not a thing which has objective existence. No one would confound the bank rate of interest with a sum of money, nor the birth or death rate of a country with a group of individual human beings. These rates are, in fact, mere abstract numbers, by the help of which a man may compute interest per annum from the amount of capital, or the number of infants per annum from the amount of the population. The gradient of temperature, in an irregularly heated body, is a mere vector-rate, by the help of which we can calculate how much energy (in the form of heat) passes in a given time across any assigned surface in the body. To attribute objectivity to a rate is even more ridiculous than it would be to attribute it to a sensation, or to a thought, or to a word or phrase which we find useful in characterizing some material object.

§ 296. On the other hand, all these different kinds of rates have been introduced and continue to be employed, because they have been found to be useful. There is no harm done by retaining them, provided those who use them know that they are introduced for convenience of expression, and not because there are objective realities corresponding to them. Even such a term as "centrifugal force" is sometimes useful; but always under the proviso that he who employs it shall remember that it is only one side of the stress under which a particle of matter is compelled, in spite of its inertia, to move in a curved line. But the term must be taken, like "algebra," "theodolite," "Abracadabra," or any other combination of letters whose derivation is uncertain or unknown, as one and indivisible, to which a certain definite meaning is attached, and as having nothing whatever to do with the meaning or derivation of the word centrifugal, whose embodiment in it is a perennial monument to the memory of an old error.

Potential energy kinetic.

§ 297. The main characteristics of energy, especially from the experimental point of view, have already been discussed under DYNAMICS (*q.v.*) and ENERGY (*q.v.*). But there is one point of importance connected with it which comes more naturally here than in either of the articles referred to.

When two measurable quantities, of any kind, are equivalent to one another, their numerical expressions must involve the same fundamental units, and in the same manner. This is obvious from the fact that an alteration of any unit alters in the inverse ratio the numerical measure of any quantity which is a mere multiple of it. And equivalent quantities must always be expressed by equal numbers when both are measured in terms of the same system of units. It appears, therefore, from the conservation of energy directly, as well as from the special data in §§ 111, 113, that potential energy must, like kinetic energy, be of dimensions  $[ML^2T^{-2}]$ .

Now it is impossible to conceive of a truly dormant form of energy whose magnitude should depend in any way on the unit of time; and we are therefore forced to the conclusion that potential energy, like kinetic energy, depends

(in some as yet unexplained, or rather unimagined, way) upon motion. For the immediate purposes of this article the question is not one of importance. We have been dealing with the more direct consequences of a very compact set of laws, exceedingly simple in themselves, originally based upon observation and experiment, and, most certainly, true. But reason cannot content itself with the mere consequences of a series of observed facts, however elegantly and concisely these may be stated by the help of new terms and their definitions. We are forced to inquire into what may underlie these definitions, and the laws which are observed to regulate the things signified by them. And the conclusion which appears inevitable is that, whatever matter may be, the other reality in the physical universe, energy, which is never found unassociated with matter, depends in all its widely varied forms upon motion of matter. In some cases we are sure, in others we can as yet only suspect, that it depends upon motions in a medium which, unlike ordinary matter, has not yet been subjected to the scrutiny of the chemist. But the question, in its generality, is one of the most obscure in the whole range of physics. In the articles ATOM, ATTRACTION, ETHER, will be found nearly all that is yet known on this profoundly difficult subject. But to what is there said must be added the remark that a state of strain of the ether, whether associated with the propagation of light and radiant heat or with a statical distribution of electricity, represents so much "potential" energy, and must in its turn in some way depend on motion.

§ 298. The remarks of Clerk Maxwell on the nature of the evidence for Newton's *first* law of motion raise a question, in some respects novel, but in all respects well worthy of careful study. He says:—

"Our conviction of the truth of this law may be greatly strengthened by considering what is involved in a denial of it. Given a body in motion. At a given instant let it be left to itself and not acted on by any force. What will happen? According to Newton's law it will persevere in moving uniformly in a straight line; that is, its velocity will remain constant both in direction and magnitude.

"If the velocity does not remain constant let us suppose it to vary. The change of velocity must have a definite direction and magnitude. By the maxim that *the same causes will always produce the same effects*, this variation must be the same whatever be the time or place of the experiment. The direction of the change of motion must therefore be determined either by the direction of the motion itself, or by some direction fixed in the body. Let us, in the first place, suppose the law to be that the velocity diminishes at a certain rate, which, for the sake of the argument, we may suppose so slow that by no experiments on moving bodies could we have detected the diminution of velocity in hundreds of years. The velocity referred to in this hypothetical law can only be the velocity referred to a point absolutely at rest. For if it is a relative velocity, its direction as well as its magnitude depends on the velocity of the point of reference. If, when referred to a certain point, the body appears to be moving northward with diminishing velocity, we have only to refer it to another point moving northward with a uniform velocity greater than that of the body, and it will appear to be moving southward with increasing velocity. Hence the hypothetical law is without meaning, unless we admit the possibility of defining absolute rest and absolute velocity. . . .

"It may thus be shown that the denial of Newton's law is in contradiction to the only system of consistent doctrine about space and time which the human mind has been able to form."

This is a good example of a valuable application of a Principle principle which, in its widest scope, is inconsistent with the true foundations of physical science. It is, in fact, the exceedingly dangerous "principle of sufficient reason"—which requires for its legitimate use the utmost talent and knowledge on the part of the user.

§ 299. But in all methods and systems which involve the idea of force there is the leaven of artificiality. The true laws of motion, based entirely on experiments of the most extensive and most varied kinds, are those of the conservation and of the transformation of energy. With the help

of kinematical ideas, it is easy to base the whole science of dynamics on these principles; and there is no necessity for the introduction of the word "force" nor of the sense-suggested ideas on which it was originally based.

§ 300. Nothing beyond a mere mention has been made above of virtual velocities, and of the so-called elementary machines. These belong to the subject of Applied Mechanics, separately treated below.

§ 301. The references which have been made to various grand theories, such as action, impulse in general, &c., have been illustrated by simple cases only. For a detailed examination of these theories the reader is referred to Thomson and Tait's *Natural Philosophy*, chap. ii. To the same work he is referred for the general "theory of small oscillations," the "dissipative function," the "ignorance of coordinates," the treatment of "gyrostatic systems" and of "kinetic stability." All of these have been exhibited, though in mere particular instances, in the preceding pages.

#### *Treatises on Mechanics.*

§ 302. The following works on Mechanics are indispensable:—

1. Newton's *Principia* (1st ed., 1687; latest ed., Glasgow, 1871). Here, for the first time, the fundamental principles were systematized, extended (as we have seen) in a most vital particular, and applied, by the aid of a new mathematical method of immense power (based entirely on kinematical considerations), to many of the most important questions of cosmical and terrestrial dynamics.

Newton's system was first taught in the university of Edinburgh; and, with brief intervals, his methods also have been habitually kept before the students there. From the time of Maclaurin to that of Forbes the value of the quasi-geometrical methods in giving a clear insight into the problems treated has rarely been overlooked. In Cambridge these methods were of later introduction, but they still deservedly figure as a necessary part of the reading of candidates for "mathematical honours." It is to be feared, however, that in some other British universities the study of Newton's methods is not prosecuted to anything like the same extent. But the very reverse seems to be the case in America, where, probably to a considerable extent on this account, mathematical physics is advancing in a most remarkable manner.

2. Lagrange's *Mécanique Analytique* (1st ed., 1788). Though objections may fairly be taken to the fundamental method of this work, there can be no question as to the immense power and originality of its author. His "generalized coordinates," and the equations of motion of a system in terms of these, form one of the most important contributions to the science since the days of Newton. The method of Lagrange, though he was not aware of the fact, is really based upon the consideration of energy; and when, in quite recent times, experiment had shown what are the grand laws of energy, Lagrange's magnificent mathematical methods and results were ready for translation into the new language of science.

3. Hamilton's papers in the *Philosophical Transactions* for 1833 and 1834. Here the principle of varying action, and the characteristic function, were first applied to mechanics;—though they had been given, some years before, to the Royal Irish Academy, in their optical applications. Grand as have been the extensions of these new ideas made by Hamilton himself, and by many others, among whom Jacobi and Liouville may be especially mentioned, they have been mainly in a purely mathematical direction. We wait for what cannot now be long delayed, the coming of the philosopher who is to tell us the true dynamical bearings of varying action and of the characteristic function.

4. If to these we add some of the works of Galileo, Huygens, Euler, Maclaurin, and D'Alembert, we have the great landmarks in the history of the subject, as distinguished from its development.

5. The mere enumeration of the more important developments which the subject has received, as distinguished from the absolutely new grand ideas and methods introduced, would require a long article. Brilliant examples of what may be done in this direction are furnished by Stokes's "Report on Recent Researches in Hydrodynamics" and by Cayley's "Reports on Theoretical Dynamics" (printed in the *British Association Reports* for 1846, and for 1857 and 1862). These should be consulted by every student who desires to trace the growth of the subject. They have been succeeded, in the same *Reports* (1880, 1881) by two excellent summaries, by Hicks, of "Recent Progress in Hydrodynamics."

But Laplace's *Mécanique Céleste*, Poisson's *Mécanique*, Poincaré's *Théorie Nouvelle de la Rotation*, &c., more or less parts of the immediate outcome of the period when France intellectually dwarfed the rest of the world, are still of far more than mere historic value.

For the English-reading student of modern times, the work of Thomson and Tait will be found suitable. The authors of this

work claim the position of "restorers," not of innovators; and they have (since 1863, when the first short sketch of their work was published) striven with success to re-establish in Britain Newton's grand yet simple foundations of the subject. But these foundations, as stated above, are only temporarily the best. We have not, *as yet*, anything nearly so good.

Other modern works of value are the *Analytic Mechanics* of the late Professor Peirce (Boston, 1855) and Kirchhoff's *Vorlesungen über Mathematische Physik* (Leipsic, 1876). Both are rather of the nature of collections of short treatises on special questions than organized wholes, but both will well repay careful reading. This, in the case of Peirce's work, is rendered extremely puzzling and laborious by the peculiar notations and modes of reference adopted by the author. It is particularly interesting to study the ways in which the fundamental principles are introduced in these works, and to compare them with the corresponding parts of the works of Newton and Lagrange. Lagrange, Peirce, and Kirchhoff construct each a system as free from anything but analysis as possible. In fact Lagrange prefaces his work by the characteristic statement, "On ne trouvera point de Figures dans cet ouvrage. Les méthodes que j'y expose ne demandent ni constructions, ni raisonnemens géométriques ou mécaniques, mais seulement des opérations algébriques, assujetties à une marche régulière et uniforme. Ceux qui aiment l'Analyse verront avec plaisir la Mécanique en devenir une nouvelle branche." . . . How far we have considered it expedient to differ from such an authority, a glance at the preceding pages will show.

A part of the detailed work of several of the examples above given in *Dynamics of a Particle* has been taken from the elementary treatise (with that title) of Tait and Steele. The English reader who wishes to pursue elementary Statics may profitably consult the treatise of Minchin. The higher parts are discussed in the work of Somoff, *Theoretische Mechanik* (Leipsic, 1879). An excellent introduction to the use of Generalized Coordinates has been published by Watson and Burbury (1879). On Lagrange's Generalized Equations the student should also read in Maxwell's *Treatise on Electricity and Magnetism*, part iv. chap. v. And Maxwell's brief treatise on *Matter and Motion* should be in the hands of every one commencing the subject.

#### ANALYSIS OF THE PRECEDING ARTICLE.

NEWTON'S LAWS OF MOTION, with Comments, assumed as the basis of the article, §§ 1-13.

KINEMATICS: Position, §§ 14-19; Kinematics of Point, §§ 20-70; of Plane Figure in its own Plane, §§ 71-74; of Rigid Figure, §§ 75-83; of Deformable Figure, §§ 84-95.

DYNAMICS OF A PARTICLE: General Considerations, §§ 96-113; Further Comments on the First Two Laws of Motion, §§ 114-119; Friction, §§ 120-121; Statics of a Particle, §§ 122-128; Kinetics of a Particle with One Degree of Freedom (Meteorite, Hailstone, Pendulum, Cycloidal and Resisted Pendulum), §§ 129-139; with Two Degrees of Freedom (Planetary Motion, Kepler's Laws and their Consequences, Kinetic Stability), §§ 140-149; The Brachistochrone, §§ 150-152; Kinetics of a Particle generally (Conical Pendulum, Blackburn's and Foucault's Pendulums, Varying Constraint, Disturbed Motion), §§ 153-163; Third Law, Kinetics of Two or More Particles (Atwood's Machine, Chain-shot, Complex Pendulum), §§ 164-178; Kinetics of Free Particles generally, Virial, § 179; Impact (Continuous Series of Infinitely Small Impacts, Rocket), §§ 180-190; Dynamics of a System of Particles generally (Equilibrium—Neutral, Stable, and Unstable; Lagrange's General Equation), §§ 191-199; Action, §§ 200-214; Generalized Coordinates, §§ 215, 216.

STATICS OF A RIGID SOLID: Reduction of Forces to Force and Couple, Mindling's Theorem, Examples of Statical Problems, §§ 217-233.

KINETICS OF A RIGID SOLID: Moment of Inertia, Binet's Theorem, Compound Pendulum, Ballistic Pendulum, Rolling and Sliding of Sphere, Motion about Fixed Point, Poincaré's and Sylvester's Constructions, Quoit, Gyroscopic Pendulum, §§ 234-257.

STATICS OF A CHAIN: Common Catenary, Catenary of Uniform Strength, Kinetic Analogy, Chain Stretched on Surface, §§ 258-264.

KINETICS OF A CHAIN: Wave Propagation, Musical String, Chain with One End Free, Impulsive Tension, Longitudinal Wave, §§ 265-270.

DYNAMICS OF ELASTIC SOLID: Flexure and Torsion of Wire, Bending of Plank, Oscillation of Flat Spring, Distortion of Cylinders and Spheres by Internal and External Hydrostatic Pressure, §§ 271-284.

GENERAL CONSIDERATIONS ABOUT FORCE AND ENERGY: Newton's Idea of Force, Origin of the Conception, Stress, Objective Physical Realities, True Nature of Force, Rates in General, Potential Energy in its Nature Kinetic, Maxwell on Inertia, True Laws of Motion, §§ 285-299.

References to Authoritative Works, §§ 301, 302.

(P. G. T.)

## APPLIED MECHANICS.

1. The practical applications of mechanics may be divided into two classes, according as the assemblages of material objects to which they relate are intended to remain fixed or to move relatively to each other,—the former class being comprehended under the term "Theory of Structures," and the latter under the term "Theory of Machines." As the details of the theory of structures are dealt with in other articles, it will be treated of here to such extent only as may be necessary in order to state certain general principles applicable to all these subjects. The greater part of the article will relate to machines.

## PART I. OUTLINE OF THE THEORY OF STRUCTURES.

2. *Support of Structures.*—Every structure, as a whole, is maintained in equilibrium by the joint action of its own weight, of the external load or pressure applied to it from without and tending to displace it, and of the resistance of the material which supports it. A structure is supported either by resting on the solid crust of the earth, as buildings do, or by floating in a fluid, as ships do in water and balloons in air. The principles of the support of a floating structure form an important part of HYDROMECHANICS (*q.v.*). The principles of the support, as a whole, of a structure resting on the land, are so far identical with those which regulate the equilibrium and stability of the several parts of that structure, and of which a summary will presently be given, that the only principle which seems to require special mention here is one which comprehends in one statement the power both of liquids and of loose earth to support structures, and which was first demonstrated in a paper "On the Stability of Loose Earth," read to the Royal Society on the 19th of June 1856, and published in the *Philosophical Transactions* for that year, viz.:—

Let  $E$  represent the weight of the portion of a horizontal stratum of earth which is displaced by the foundation of a structure,  $S$  the utmost weight of that structure consistently with the power of the earth to resist displacement,  $\phi$  the angle of repose of the earth; then

$$\frac{S}{E} = \left( \frac{1 + \sin \phi}{1 - \sin \phi} \right)^2.$$

To apply this to liquids,  $\phi$  must be made  $= 0$ , and then  $\frac{S}{E} = 1$ , as is well known.

3. *Composition of a Structure, and Connexion of its Pieces.*—A structure is composed of *pieces*,—such as the stones of a building in masonry, the beams of a timber frame-work, the bars, plates, and bolts of an iron bridge. Those pieces are connected at their *joints* or surfaces of mutual contact, either by simple pressure and friction (as in masonry with moist mortar or without mortar), by pressure and adhesion (as in masonry with cement or with hardened mortar, and timber with glue), or by the resistance of *fastenings* of different kinds, whether made by means of the form of the joint (as dovetails, notches, mortises, and tenons) or by separate fastening pieces (as trenails, pins, spikes, nails, holdfasts, screws, bolts, rivets, hoops, straps, and sockets).

4. *Stability, Stiffness, and Strength.*—A structure may be damaged or destroyed in three ways:—first, by *displacement* of its pieces from their proper positions relatively to each other or to the earth; secondly, by *disfigurement* of one or more of those pieces, owing to their being unable to preserve their proper shapes under the pressures to which they are subjected; thirdly, by *breaking* of one or more of those pieces. The power of resisting displacement constitutes *stability*; the power of each piece to resist disfigurement is its *stiffness*; and its power to resist breaking, its *strength*.

5. *Conditions of Stability.*—The principles of the stability of a structure can be to a certain extent investigated independently of the stiffness and strength, by assuming, in the first instance, that each piece has strength sufficient to be safe against being broken, and stiffness sufficient to prevent its being disfigured to an extent inconsistent with the purposes of the structure, by the greatest forces which are to be applied to it. The condition that each piece of the structure is to be maintained in equilibrium by having its gross load, consisting of its own weight and of the external pressure applied to it, balanced by the *resistances* or pressures exerted between it and the contiguous pieces, furnishes the means of determining the magnitude, position, and direction of the resistances required at each joint in order to produce equilibrium; and the *conditions of stability* are, first, that the *position*, and, secondly, that the *direction*, of the resistance required at each joint shall, under all the variations to which the load is subject, be such as the joint is capable of exerting,—conditions which are fulfilled by suitably adjusting the figures and positions of the joints, and the *ratios* of the gross loads of the pieces. As for the *magnitude* of the resistance, it is limited by conditions, not of stability, but of strength and stiffness.

6. *Principle of Least Resistance.*—Where more than one system of resistances are alike capable of balancing the same system of loads

applied to a given structure, it has been demonstrated by Moseley that the *smallest* of those alternative systems is that which will actually be exerted,—because the resistances to displacement are the effect of a strained state of the pieces, which strained state is the effect of the load, and when the load is applied the strained state and the resistances produced by it increase until the resistances acquire just those magnitudes which are sufficient to balance the load, after which they increase no further.

This principle of least resistance renders determinate many problems in the statics of structures which were formerly considered indeterminate.

7. *Relations between Polygons of Loads and of Resistances.*—In a structure in which each piece is supported at two joints only, the well-known laws of statics show that the directions of the gross load on each piece and of the two resistances by which it is supported must lie in one plane, must either be parallel or meet in one point, and must bear to each other, if not parallel, the proportions of the sides of a triangle respectively parallel to their directions, and, if parallel, such proportions that each of the three forces shall be proportional to the distance between the other two,—all the three distances being measured along one direction.

Considering, in the first place, the case in which the load and the two resistances by which each piece is balanced meet in one point, which may be called the *centre of load*, there will be as many such points of intersection, or centres of load, as there are pieces in the structure; and the directions and positions of the resistances or mutual pressures exerted between the pieces will be represented by the sides of a polygon joining those points, as in fig. 1, where  $P_1, P_2, P_3, P_4$  represent the centres of load in a structure of four pieces, and the sides of the polygon of resistances  $P_1P_2P_3P_4$  represent respectively the directions and position of the resistances exerted at the joints. Further, at any one of the centres of load let  $PL$  represent the magnitude and direction of the gross load, and  $Pa, Pb$  the two resistances by which the piece to which that load is applied is supported; then will those three lines be respectively the diagonal and sides of a parallelogram; or, what is the same thing, they will be equal to the three sides of a triangle; and they must be in the same plane, although the sides of the polygon of resistances may be in different planes.

According to a well-known principle of statics, because the loads or external pressures  $P_1, L_1$ , &c., balance each other, they must be proportional to the sides of a closed polygon drawn respectively parallel to their directions. In fig. 2 construct such a polygon of loads by drawing the lines  $L_1$ , &c., parallel and proportional to, and joined end to end in the order of, the gross loads on the pieces of the structure. Then from the proportionality and parallelism of the load and the two resistances applied to each piece of the structure to the three sides of a triangle, there results the following theorem [originally due to Rankine]:—

If from the angles of the polygon of loads there be drawn lines ( $R_1, R_2$ , &c.), each of which is parallel to the resistance (as  $P_1P_2$ , &c.) exerted at the joint between the pieces to which the two loads represented by the contiguous sides of the polygon of loads (such as  $L_1, L_2$ , &c.) are applied; then will all those lines meet in one point ( $O$ ), and their lengths, measured from that point to the angles of the polygon, will represent the magnitudes of the resistances to which they are respectively parallel.

When the load on one of the pieces is parallel to the resistances which balance it, the polygon of resistances ceases to be closed, two of the sides becoming parallel to each other and to the load in question, and extending indefinitely. In the polygon of loads the direction of a load sustained by parallel resistances traverses the point  $O$ .

8. *How the Earth's Resistance is to be treated.*—When the pressure exerted by a structure on the earth (to which the earth's resistance is equal and opposite) consists either of one pressure, which is necessarily the resultant of the weight of the structure and of all the other forces applied to it, or of two or more parallel vertical forces, whose amount can be determined at the outset of the

Fig. 1.

Fig. 2.

investigation, the resistance of the earth can be treated as one or more *upward loads* applied to the structure. But in other cases the earth is to be treated as *one of the pieces of the structure*, loaded with a force equal and opposite in direction and position to the resultant of the weight of the structure and of the other pressures applied to it.

9. *Partial Polygons of Resistance.*—In a structure in which there are pieces supported at more than two joints, let a polygon be constructed of lines connecting the centres of load of any continuous series of pieces. This may be called a *partial polygon of resistances*. In considering its properties, the load at each centre of load is to be held to include the resistances of those joints which are not comprehended in the partial polygon of resistances, to which the theorem of section 7 will then apply in every respect. By constructing several partial polygons, and computing the relations between the loads and resistances which are determined by the application of that theorem to each of them, with the aid, if necessary, of Moseley's principle of the least resistance, the whole of the relations amongst the loads and resistances may be found.

10. *Line of Pressures—Centres and Line of Resistance.*—The line of pressures is a line to which the directions of all the resistances in one polygon are tangents. The centre of resistance at any joint is the point where the line representing the total resistance exerted at that joint intersects the joint. The line of resistance is a line traversing all the centres of resistance of a series of joints,—its form, in the positions intermediate between the actual joints of the structure, being determined by supposing the pieces and their loads to be subdivided by the introduction of intermediate joints *ad infinitum*, and finding the continuous line, curved or straight, in which the intermediate centres of resistance are all situated, however great their number. The difference between the line of resistance and the line of pressures was first pointed out by Moseley.

11. *Stability of Position, and Stability of Friction.*—The resistances at the several joints having been determined by the principles set forth in sections 6, 7, 8, 9, and 10, not only under the ordinary load of the structure, but under all the variations to which the load is subject as to amount and distribution, the joints are now to be placed and shaped so that the pieces shall not suffer relative displacement under any of those loads. The relative displacement of the two pieces which abut against each other at a joint may take place either by turning or by sliding. Safety against displacement by turning is called *stability of position*; safety against displacement by sliding, *stability of friction*.

12. *Condition of Stability of Position.*—If the materials of a structure were infinitely stiff and strong, stability of position at any joint would be insured simply by making the centre of resistance fall within the joint under all possible variations of load. In order to allow for the finite stiffness and strength of materials, the least distance of the centre of resistance inward from the nearest edge of the joint is made to bear a definite proportion to the depth of the joint measured in the same direction, which proportion is fixed, sometimes empirically, sometimes by theoretical deduction from the laws of the strength of materials. That least distance is called by Moseley the *modulus of stability*. The following are some of the ratios of the modulus of stability to the depth of the joint which occur in practice:—

|  |            |
|--|------------|
| Retaining walls, as designed by British engineers.....                               | 1:8        |
| Retaining walls, as designed by French engineers.....                                | 1:5        |
| Rectangular piers of bridges and other buildings, and arch-stones.                   | 1:3        |
| Rectangular foundations, firm ground.....  | 1:3        |
| Rectangular foundations, very soft ground.....                                       | 1:2        |
| Rectangular foundations, intermediate kinds of ground.....                           | 1:3 to 1:2 |
| Thin, hollow towers (such as furnace chimneys exposed to high winds), square.....    | 1:6        |
| Thin, hollow towers, circular.....   | 1:4        |
| Frames of timber or metal, under their ordinary or average distribution of load..... | 1:3        |
| Frames of timber or metal, under the greatest irregularities of load.....            | 1:8        |

In the case of the towers, the *depth of the joint* is to be understood to mean the *diameter of the tower*.

13. *Condition of Stability of Friction.*—If the resistance to be exerted at a joint is always perpendicular to the surfaces which abut at and form that joint, there is no tendency of the pieces to be displaced by sliding. If the resistance be oblique, let JK (fig. 3) be the joint, C its centre of resistance, CR a line representing the resistance, CN a perpendicular to the joint at the centre of resistance. The angle NCR is the *obliquity of the resistance*. From R draw RP parallel and RQ perpendicular to the joint; then, by the principles of statics, the component of the resistance *normal* to the joint is—

$$CP = CR \cdot \cos \angle PRC;$$

and the component *tangential* to the joint is—

$$CQ = CR \cdot \sin \angle PCR = CP \cdot \tan \angle PCR.$$

Fig. 3.

If the joint be provided either with projections and recesses, such as mortises and tenons, or with fastenings, such as pins or bolts, so as to resist displacement by sliding, the question of the utmost amount of the tangential resistance CQ which it is capable of exerting depends on the *strength* of such projections, recesses, or fastenings, and belongs to the subject of strength, and not to that of stability. In other cases the safety of the joint against displacement by sliding depends on its power of exerting friction, and that power depends on the law, known by experiment, that the friction between two surfaces bears a constant ratio, depending on the nature of the surfaces, to the force by which they are pressed together. In order that the surfaces which abut at the joint JK may be pressed together, the resistance required by the conditions of equilibrium, CR, must be a *thrust* and not a *pull*; and in that case the force by which the surfaces are pressed together is equal and opposite to the normal component CP of the resistance. The condition of stability of friction is that the tangential component CQ of the resistance required shall not exceed the friction due to the normal component; that is, that

$$CQ \nless f \cdot CP,$$

where *f* denotes the *coefficient of friction* for the surfaces in question. The angle whose tangent is the coefficient of friction is called the *angle of repose*, and is expressed symbolically by—

$$\phi = \tan^{-1} f.$$

$$\text{Now } CQ = CP \cdot \tan \angle PCR;$$

consequently the condition of stability of friction is fulfilled if

$$\angle PCR \nless \phi;$$

that is to say, if the *obliquity of the resistance required at the joint does not exceed the angle of repose*; and this condition ought to be fulfilled under all possible variations of the load.

It is chiefly in masonry and earthwork that stability of friction is relied on.

14. *Stability of Friction in Earth.*—The grains of a mass of loose earth are to be regarded as so many separate pieces abutting against each other at joints in all possible positions, and depending for their stability on friction. To determine whether a mass of earth is stable at a given point, conceive that point to be traversed by planes in all possible positions, and determine which position gives the greatest obliquity to the total pressure exerted between the portions of the mass which abut against each other at the plane. The condition of stability is that this obliquity shall not exceed the angle of repose of the earth. The consequences of this principle are developed in a paper "On the Stability of Loose Earth," already cited in sect. 2.

15. *Parallel Projections of Figures.*—If any figure be referred to a system of coordinates, rectangular or oblique, and if a second figure be constructed by means of a second system of coordinates, rectangular or oblique, and either agreeing with or differing from the first system in rectangularity or obliquity, but so related to the coordinates of the first figure that for each point in the first figure there shall be a corresponding point in the second figure, the lengths of whose coordinates shall bear respectively to the three corresponding coordinates of the corresponding point in the first figure three ratios which are the same for every pair of corresponding points in the two figures, these corresponding figures are called *parallel projections* of each other. The properties of parallel projections of most importance to the subject of the present article are the following:—

- (1) A parallel projection of a straight line is a straight line.
- (2) A parallel projection of a plane is a plane.
- (3) A parallel projection of a straight line or a plane surface divided in a given ratio is a straight line or a plane surface divided in the same ratio.
- (4) A parallel projection of a pair of equal and parallel straight lines, or plain surfaces, is a pair of equal and parallel straight lines, or plane surfaces; whence it follows
- (5) That a parallel projection of a parallelogram is a parallelogram, and
- (6) That a parallel projection of a parallelepiped is a parallelepiped.
- (7) A parallel projection of a pair of solids having a given ratio is a pair of solids having the same ratio.

Though not essential for the purposes of the present article, the following consequence will serve to illustrate the principle of parallel projections:—

- (8) A parallel projection of a curve, or of a surface of a given algebraical order, is a curve or a surface of the same order.

For example, all ellipsoids referred to coordinates parallel to any three conjugate diameters are parallel projections of each other and of a sphere referred to rectangular coordinates.

16. *Parallel Projections of Systems of Forces.*—If a balanced system of forces be represented by a system of lines, then will every parallel projection of that system of lines represent a balanced system of forces.

For the condition of equilibrium of forces not parallel is that they shall be represented in direction and magnitude by the sides and diagonals of certain parallelograms, and of parallel forces that they shall divide certain straight lines in certain ratios; and the parallel projection of a parallelogram is a parallelogram, and that of a straight line divided in a given ratio is a straight line divided in the same ratio.

The resultant of a parallel projection of any system of forces is the projection of their resultant; and the centre of gravity of a parallel projection of a solid is the projection of the centre of gravity of the first solid.

17. *Principle of the Transformation of Structures.*—Here we have the following theorem:—If a structure of a given figure have stability of position under a system of forces represented by a given system of lines, then will any structure whose figure is a parallel projection of that of the first structure have stability of position under a system of forces represented by the corresponding projection of the first system of lines.

For in the second structure the weights, external pressures, and resistances will balance each other as in the first structure; the weights of the pieces and all other parallel systems of forces will have the same ratios as in the first structure; and the several centres of resistance will divide the depths of the joints in the same proportions as in the first structure.

If the first structure have stability of friction, the second structure will have stability of friction also, so long as the effect of the projection is not to increase the obliquity of the resistance at any joint beyond the angle of repose.

The lines representing the forces in the second figure show their relative directions and magnitudes. To find their absolute directions and magnitudes, a vertical line is to be drawn in the first figure, of such a length as to represent the weight of a particular portion of the structure. Then will the projection of that line in the projected figure indicate the vertical direction, and represent the weight of the part of the second structure corresponding to the before-mentioned portion of the first structure.

The foregoing "principle of the transformation of structures" was first announced, though in a somewhat less comprehensive form, to the Royal Society on the 6th of March 1856. It is useful in practice, by enabling the engineer easily to deduce the conditions of equilibrium and stability of structures of complex and unsymmetrical figures from those of structures of simple and symmetrical figures. By its aid, for example, the whole of the properties of elliptical arches, whether square or skew, whether level or sloping in their span, are at once deduced by projection from those of symmetrical circular arches, and the properties of ellipsoidal and elliptic-conoidal domes from those of hemispherical and circular-conoidal domes; and the figures of arches fitted to resist the thrust of earth, which is less horizontally than vertically in a certain given ratio, can be deduced by a projection from those of arches fitted to resist the thrust of a liquid, which is of equal intensity, horizontally and vertically.

18. *Conditions of Stiffness and Strength.*—After the arrangement of the pieces of a structure and the size and figure of their joints or surfaces of contact have been determined so as to fulfil the conditions of stability,—conditions which depend mainly on the position and direction of the resultant or total load on each piece, and the relative magnitude of the loads on the different pieces,—the dimensions of each piece singly have to be adjusted so as to fulfil the conditions of stiffness and strength,—conditions which depend not only on the absolute magnitude of the load on each piece, and of the resistances by which it is balanced, but also on the mode of distribution of the load over the piece, and of the resistances over the joints.

The effect of the pressures applied to a piece, consisting of the load and the supporting resistances, is to force the piece into a state of strain or disfigurement, which increases until the elasticity, or resistance to strain, of the material causes it to exert a stress, or effort to recover its figure, equal and opposite to the system of applied pressures. The condition of stiffness is that the strain or disfigurement shall not be greater than is consistent with the purposes of the structure; and the condition of strength is that the stress shall be within the limits of that which the material can bear with safety against breaking. The ratio in which the utmost stress before breaking exceeds the safe working stress is called the *factor of safety*, and is determined empirically. It varies from three to twelve for various materials and structures.

The STRENGTH OF MATERIALS forms the subject of a special article, to which the reader is referred.

## PART II. THEORY OF MACHINES.

19. *Parts of a Machine—Frame and Mechanism.*—The parts of a machine may be distinguished into two principal divisions,—the frame, or fixed parts, and the mechanism, or moving parts. The frame is a structure which supports the pieces of the mechanism, and to a certain extent determines the nature of their motions.

The form and arrangement of the pieces of the frame depend upon the arrangement and the motions of the mechanism; the dimensions of the pieces of the frame required in order to give it stability and strength are determined from the pressures applied to it by means of the mechanism. It appears therefore that in general the mechanism is to be designed first and the frame afterwards, and that the designing of the frame is regulated by the principles of the stability of structures and of the strength and stiffness of materials,—care being taken to adapt the frame to the most severe load which can be thrown upon it at any period of the action of the mechanism.

Each independent piece of the mechanism also is a structure, and its dimensions are to be adapted, according to the principles of the strength and stiffness of materials, to the most severe load to which it can be subjected during the action of the machine.

20. *Definition and Division of the Theory of Machines.*—From what has been said in the last section it appears that the department of the art of designing machines which has reference to the stability of the frame and to the stiffness and strength of the frame and mechanism is a branch of the art of construction. It is therefore to be separated from the *theory of machines*, properly speaking, which has reference to the action of machines considered as moving. In the action of a machine the following three things take place:—

*First*, Some natural source of energy communicates motion and force to a piece or pieces of the mechanism, called the *receiver of power* or *prime mover*.

*Secondly*, The motion and force are transmitted from the prime mover through the *train of mechanism* to the *working piece* or *pieces*, and during that transmission the motion and force are modified in amount and direction, so as to be rendered suitable for the purpose to which they are to be applied.

*Thirdly*, The working piece or pieces by their motion, or by their motion and force combined, produce some useful effect.

Such are the phenomena of the action of a machine, arranged in the order of causation. But in studying or treating of the theory of machines, the order of *simplicity* is the best; and in this order the first branch of the subject is the modification of motion and force by the train of mechanism; the next is the effect or purpose of the machine; and the last, or most complex, is the action of the prime mover.

The modification of motion and the modification of force take place together, and are connected by certain laws; but in the study of the theory of machines, as well as in that of pure mechanics, much advantage has been gained in point of clearness and simplicity by first considering alone the principles of the modification of motion, which are founded upon what is now known as Kinematics, and afterwards considering the principles of the combined modification of motion and force, which are founded both on geometry and on the laws of dynamics. The separation of kinematics from dynamics is due mainly to Monge, Ampère, and Willis.

The theory of machines in the present article will be considered under the following four heads:—

- I. PURE MECHANISM, or APPLIED KINEMATICS; being the theory of machines considered simply as modifying motion.
- II. APPLIED DYNAMICS; being the theory of machines considered as modifying both motion and force.
- III. PURPOSES AND EFFECTS OF MACHINES.
- IV. APPLIED ENERGETICS; being the theory of prime movers and sources of power.

### CHAP. I. ON PURE MECHANISM.

21. *Division of the Subject.*—Proceeding in the order of simplicity, the subject of Pure Mechanism, or Applied Kinematics, may be thus divided:—

- Division 1.*—Motion of a point.
- Division 2.*—Motion of the surface of a fluid.
- Division 3.*—Motion of a rigid solid.
- Division 4.*—Motions of a pair of connected pieces, or of an "elementary combination" in mechanism.
- Division 5.*—Motions of trains of pieces of mechanism.
- Division 6.*—Motions of sets of more than two connected pieces, or of "aggregate combinations."

A point is the boundary of a line, which is the boundary of a surface, which is the boundary of a volume. Points, lines, and surfaces have no independent existence, and consequently those divisions of this chapter which relate to their motions are only preliminary to the subsequent divisions, which relate to the motions of bodies.

#### *Division 1. Motion of a Point.*

22. *Path and Direction.*—See above, p. 679, § 21.

23. *Uniform Velocity.*—See p. 680, § 25.

24. *Varied Velocity.*—See p. 680, § 25.

25. *Direct Deviation, or Acceleration and Retardation.*—See pp. 680, 681, §§ 27–29.

26. *Lateral Deviation or Deflection—Angular Velocity of Deviation—Revolution.*—See pp. 681, 682, §§ 31–38.

27. *Comparative Motion.*—The comparative motion of two points is the relation which exists between their motions, without having regard to their absolute amounts. It consists of two elements,—the *velocity ratio*, which is the ratio of any two magnitudes bearing to each other the proportions of the respective velocities of the two points at a given instant, and the *directional relation*, which is the relation borne to each other by the respective directions of the motions of the two points at the same given instant.

It is obvious that the motions of a pair of points may be varied in any manner, whether, by direct or by lateral deviation, and yet that their comparative motion may remain constant, in consequence of the deviations taking place in the same proportions, in the same directions, and at the same instants for both points.

Willis has the merit of having been the first to simplify considerably the theory of pure mechanism, by pointing out that that branch of mechanics relates wholly to comparative motions.

The comparative motion of two points at a given instant is capable of being completely expressed by one of Sir William Hamilton's Quaternions,—the "tensor" expressing the velocity ratio, and the "versor" the directional relation.

28. *Resolution and Composition of Motion.*—See p. 681, §§ 30, 31.

29. *Rectangular Projection, Resolution, and Composition.*—See p. 681, § 31.

30. *Resolution and Composition of Deviations.*—See p. 681, § 31.

#### Division 2. Motion of the Surface of a Fluid Mass.

31. *General Principle.*—A mass of fluid is used in mechanism to transmit motion and force between two or more movable portions (called *pistons* or *plungers*) of the solid envelope or vessel in which the fluid is contained; and, when such transmission is the sole action, or the only appreciable action of the fluid mass, its volume is either absolutely constant, by reason of its temperature and pressure being maintained constant, or not sensibly varied.

Let  $a$  represent the area of the section of a piston made by a plane perpendicular to its direction of motion, and  $v$  its velocity, which is to be considered as positive when outward, and negative when inward. Then the variation of the cubic contents of the vessel in a unit of time by reason of the motion of one piston is  $va$ . The condition that the volume of the fluid mass shall remain unchanged requires that there shall be more than one piston, and that the velocities and areas of the pistons shall be connected by the equation—

$$\Sigma . va = 0 \dots \dots \dots (1).$$

32. *Comparative Motion of two Pistons.*—If there be but two pistons, whose areas are  $a_1$  and  $a_2$ , and their velocities  $v_1$  and  $v_2$ , their comparative motion is expressed by the equation—

$$\frac{v_2}{v_1} = -\frac{a_1}{a_2} \dots \dots \dots (2);$$

that is to say, their velocities are opposite as to inwardness and outwardness, and inversely proportional to their areas.

33. *Applications—Hydraulic Press—Pneumatic Power-Transmitter.*—In the hydraulic press the vessel consists of two cylinders, viz., the pump-barrel and the press-barrel, each having its piston, and of a passage connecting them having a valve opening towards the press-barrel. The action of the enclosed water in transmitting motion takes place during the inward stroke of the pump-plunger, when the above-mentioned valve is open; and at that time the press-plunger moves outwards with a velocity which is less than the inward velocity of the pump-plunger, in the same ratio that the area of the pump-plunger is less than the area of the press-plunger. (See HYDROMECHANICS.)

In the pneumatic power-transmitter the motion of one piston is transmitted to another at a distance by means of a mass of air contained in two cylinders and an intervening tube. When the pressure and temperature of the air can be maintained constant, this machine fulfils equation 2, like the hydraulic press. The amount and effect of the variations of pressure and temperature undergone by the air depend on the principles of the mechanical action of heat, or THERMODYNAMICS (*q.v.*), and are foreign to the subject of pure mechanism.

#### Division 3. Motion of a Rigid Solid.

34. *Motions Classed.*—In problems of mechanism, each solid piece of the machine is supposed to be so stiff and strong as not to undergo any sensible change of figure or dimensions by the forces applied to it,—a supposition which is realized in practice if the machine is skilfully designed.

This being the case, the various possible motions of a rigid solid body may all be classed under the following heads:—(1) *Shifting or Translation*; (2) *Turning or Rotation*; (3) *Motions compounded of Shifting and Turning.*

The most common forms for the paths of the points of a piece of mechanism, whose motion is simple shifting, are the straight line and the circle.

Shifting in a straight line is regulated either by straight fixed guides, in contact with which the moving piece slides, or by combinations of link-work, called *parallel motions*, which will be described in the sequel. Shifting in a straight line is usually *reciprocating*; that is to say, the piece, after shifting through a certain distance, returns to its original position by reversing its motion.

Circular shifting is regulated by attaching two or more points of the shifting piece to ends of equal and parallel rotating cranks, or by combinations of wheel-work to be afterwards described. As an example of circular shifting may be cited the motion of the coupling rod, by which the parallel and equal cranks upon two or more axles of a locomotive engine are connected and made to rotate simultaneously. The coupling rod remains always parallel to itself, and all its points describe equal and similar circles relatively to the frame of the engine, and move in parallel directions with equal velocities at the same instant.

35. *Rotation about a Fixed Axis—Lever, Wheel, and Axle.*—The fixed axis of a turning body is a line fixed relatively to the body and relatively to the fixed space in which the body turns. In mechanism it is usually the central line either of a rotating shaft or axle having journals, gudgeons, or pivots turning in fixed bearings, or of a fixed spindle or dead centre round which a rotating bush turns; but it may sometimes be entirely beyond the limits of the turning body. For example, if a sliding piece moves in circular fixed guides, that piece rotates about an ideal fixed axis traversing the centre of those guides.

Let the angular velocity of the rotation be denoted by  $\alpha = \frac{d\theta}{dt}$ , then the linear velocity of any point A at the distance  $r$  from the axis is  $\alpha r$ ; and the path of that point is a circle of the radius  $r$  described about the axis.

This is the principle of the modification of motion by the lever, which consists of a rigid body turning about a fixed axis called a fulcrum, and having two points at the same or different distances from that axis, and in the same or different directions, one of which receives motion and the other transmits motion, modified in direction and velocity according to the above law.

In the wheel and axle, motion is received and transmitted by two cylindrical surfaces of different radii described about their common fixed axis of turning, their velocity-ratio being that of their radii.

36. *Velocity Ratio of Components of Motion.*—As the distance between any two points in a rigid body is invariable, the projections of their velocities upon the line joining them must be equal. Hence it follows that, if A in fig. 4 be a point in a rigid body CD, rotating round the fixed axis F, the component of the velocity of A in any direction AP parallel to the plane of rotation is equal to the total velocity of the point  $m$ , found by letting fall Fm perpendicular to AP; that is to say, is equal to  $a \cdot Fm$ .

Fig. 4.

Hence also the ratio of the components of the velocities of two points A and B in the directions AP and BW respectively, both in the plane of rotation, is equal to the ratio of the perpendiculars Fm and Fn.

37. *Instantaneous Axis of a Cylinder rolling on a Cylinder.*—Let a cylinder  $bbb$ , whose axis of figure is B and angular velocity  $\gamma$ , roll on a fixed cylinder  $aaa$ , whose axis of figure is A, either outside (as in fig. 5), when the rolling will be towards the same hand as the

Fig. 5.

Fig. 6.

rotation, or inside (as in fig. 6), when the rolling will be towards the opposite hand; and at a given instant let T be the line of contact of the two cylindrical surfaces, which is at their common intersection with the plane AB traversing the two axes of figure.

The line T on the surface  $bbb$  has for the instant no velocity in

a direction perpendicular to AB; because for the instant it touches, without sliding, the line T on the fixed surface *aaa*.

The line T on the surface *bbb* has also for the instant no velocity in the plane AB; for it has just ceased to move towards the fixed surface *aaa*, and is just about to begin to move away from that surface.

The line of contact T, therefore, on the surface of the cylinder *bbb*, is for the instant at rest, and is the "instantaneous axis" about which the cylinder *bbb* turns, together with any body rigidly attached to that cylinder.

To find, then, the direction and velocity at the given instant of any point P, either in or rigidly attached to the rolling cylinder T, draw the plane PT; the direction of motion of P will be perpendicular to that plane, and towards the right or left hand according to the direction of the rotation of *bbb*; and the velocity of P will be

$$v_P = \gamma \cdot PT \quad (3),$$

PT denoting the perpendicular distance of P from T. The path of P is a curve of the kind called *epitrochoids*. If P is in the circumference of *bbb*, that path becomes an *epicycloid*.

The velocity of any point in the axis of figure B is

$$v_B = \gamma \cdot TB \quad (4);$$

and the path of such a point is a circle described about A with the radius AB, being for outside rolling the sum, and for inside rolling the difference, of the radii of the cylinders.

Let  $\alpha$  denote the angular velocity with which the plane of axes AB rotates about the fixed axis A. Then it is evident that

$$v_B = \alpha \cdot AB \quad (5),$$

and consequently that  $\alpha = \gamma \cdot \frac{TB}{AB} \quad (6).$

For internal rolling, as in fig. 6, AB is to be treated as negative, which will give a negative value to  $\alpha$ , indicating that in this case the rotation of AB round A is contrary to that of the cylinder *bbb*.

The angular velocity of the rolling cylinder, *relatively to the plane of axes AB*, is obviously given by the equation—

$$\left. \begin{aligned} \beta &= \gamma - \alpha; \\ \text{whence } \beta &= \gamma \cdot \frac{TA}{AB} \end{aligned} \right\} \quad (7);$$

care being taken to attend to the sign of  $\alpha$ , so that when that is negative the arithmetical values of  $\gamma$  and  $\alpha$  are to be added in order to give that of  $\beta$ .

The whole of the foregoing reasonings are applicable, not merely when *aaa* and *bbb* are actual cylinders, but also when they are the osculating cylinders of a pair of cylindroidal surfaces of varying curvature, A and B being the axes of curvature of the parts of those surfaces which are in contact for the instant under consideration.

38. *Composition and Resolution of Rotations about Parallel Axes.*—See above, p. 691, § 73.

39. *Instantaneous Axis of a Cone rolling on a Cone.*—Let *Oaa* (fig. 7) be a fixed cone, OA its axis, *Obb* a cone rolling on it, OB the axis of the rolling cone, OT the line of contact of the two cones at the instant under consideration. By reasoning similar to that of sect. 37, it appears that OT is the instantaneous axis of rotation of the rolling cone.

Let  $\gamma$  denote the total angular velocity of the rotation of the cone B about the instantaneous axis,  $\beta$  its angular velocity about the axis OB *relatively to the plane AOB*, and  $\alpha$  the angular velocity with which the plane AOB turns round the axis OA. It is required to find the ratios of those angular velocities.

*Solution.*—In OT take any point E, from which draw EC parallel to OA, and ED parallel to OB, so as to construct the parallelogram OCED. Then

$$\left. \begin{aligned} OD : OC : OE \\ :: \alpha : \beta : \gamma \end{aligned} \right\} \quad (8).$$

Or because of the proportionality of the sides of triangles to the sines of the opposite angles,

$$\left. \begin{aligned} \sin \angle TOB : \sin \angle TOA : \sin \angle AOB \\ :: \alpha : \beta : \gamma \end{aligned} \right\} \quad (8, A);$$

that is to say, the angular velocity about each axis is proportional to the sine of the angle between the other two.

*Demonstration.*—From C draw CF perpendicular to OA, and CG perpendicular to OE.

$$\text{Then } CF = 2 \times \frac{\text{area } ECO}{CE},$$

$$\text{and } CG = 2 \times \frac{\text{area } ECO}{OE};$$

$$\therefore CG : CF :: CE : OE.$$

Let  $v_c$  denote the linear velocity of the point C. Then

$$v_c = \alpha \cdot CF = \gamma \cdot CG$$

$$\therefore \gamma : \alpha :: CF : CG :: OE : OD,$$

which is one part of the solution above stated. From E draw EH perpendicular to OB, and EK to OA. Then it can be shown as before that

$$EK : EH :: OC : OD.$$

Let  $v_e$  be the linear velocity of the point E, *fixed in the plane of axes AOB*. Then

$$v_e = \alpha \cdot EK.$$

Now, as the line of contact OT is for the instant at rest on the rolling cone as well as on the fixed cone, the linear velocity of the point E fixed to the plane AOB *relatively to the rolling cone* is the same with its velocity *relatively to the fixed cone*. That is to say,

$$\beta \cdot EH = v_e = \alpha \cdot EK;$$

therefore

$$\alpha : \beta :: EH : EK :: OD : OC,$$

which is the remainder of the solution.

The path of a point P in or attached to the rolling cone is a spherical epitrochoid traced on the surface of a sphere of the radius OP. From P draw PQ perpendicular to the instantaneous axis. Then the motion of P is perpendicular to the plane OPQ, and its velocity is

$$v_P = \gamma \cdot PQ. \quad (9).$$

The whole of the foregoing reasonings are applicable, not merely when A and B are actual regular cones, but also when they are the osculating regular cones of a pair of irregular conical surfaces, having a common apex at O.

40. *Composition of Rotations about Two Axes meeting in a Point.*—See p. 691, § 76.

41. *Screw-like or Helical Motion.*—Since (see p. 690, §§ 71, 72) any displacement in a plane can be represented in general by a rotation, it follows that the only combination of translation and rotation, in which a complex movement which is not a mere rotation is produced, occurs when there is a translation *perpendicular to the plane and parallel to the axis of rotation*.

Such a complex motion is called *screw-like or helical motion*; for each point in the body describes a *helix or screw* round the axis of rotation, fixed or instantaneous as the case may be. To cause a body to move in this manner it is usually made of a helical or screw-like figure, and moves in a guide of a corresponding figure. Helical motion and screws adapted to it are said to be right- or left-handed according to the appearance presented by the rotation to an observer looking towards the direction of the translation. Thus the screw G in fig. 8 is right-handed.

The translation of a body in helical motion is called its *advance*. Let  $v_z$  denote the velocity of advance at a given instant, which of course is common to all the particles of the body;  $\alpha$  the angular velocity of the rotation at the same instant;  $2\pi = 6.2832$  nearly, the circumference of a circle of the radius unity. Then

$$T = \frac{2\pi}{\alpha} \quad (10)$$

is the time of one turn at the rate  $\alpha$ ; and

$$p = v_z T = \frac{2\pi v_z}{\alpha} \quad (11)$$

is the *pitch or advance per turn*,—a length which expresses the *comparative motion of the translation and the rotation*.

The pitch of a screw is the distance, measured parallel to its axis, between two successive turns of the same *thread* or helical projection.

Let  $r$  denote the perpendicular distance of a point in a body moving helically from the axis. Then

$$v_r = \alpha r \quad (12)$$

is the component of the velocity of that point in a plane perpendicular to the axis, and its total velocity is

$$v = \sqrt{v_z^2 + v_r^2} \quad (13).$$

The ratio of the two components of that velocity is

$$\frac{v_z}{v_r} = \frac{p}{2\pi r} = \tan \theta \quad (14);$$

where  $\theta$  denotes the angle made by the helical path of the point with a plane perpendicular to the axis.

Fig. 8.

42. *To find the Motion of a Rigid Body from the Motions of Three Points in it.*—See p. 690, § 71, and p. 692, § 78.

#### Division 4. Elementary Combinations in Mechanism.

43. *Definitions.*—An elementary combination in mechanism consists of two pieces whose kinds of motion are determined by their connexion with the frame, and their comparative motion by their connexion with each other,—that connexion being effected either by direct contact of the pieces, or by a connecting piece, which is not connected with the frame, and whose motion depends entirely on the motions of the pieces which it connects.

The piece whose motion is the cause is called the *driver*; the piece whose motion is the effect, the *follower*.

The connexion of each of those two pieces with the frame is in general such as to determine the path of every point in it. In the investigation, therefore, of the comparative motion of the driver and follower, in an elementary combination, it is unnecessary to consider relations of angular direction, which are already fixed by the connexion of each piece with the frame; so that the inquiry is confined to the determination of the velocity ratio, and of the directional relation, so far only as it expresses the connexion between *forward* and *backward* movements of the driver and follower. When a continuous motion of the driver produces a continuous motion of the follower, forward or backward, and a reciprocating motion a motion reciprocating at the same instant, the directional relation is said to be *constant*. When a continuous motion produces a reciprocating motion, or *vice versa*, or when a reciprocating motion produces a motion not reciprocating at the same instant, the directional relation is said to be *variable*.

The *line of action* or of *connexion* of the driver and follower is a line traversing a pair of points in the driver and follower respectively, which are so connected that the component of their velocity relatively to each other, resolved along the line of connexion, is null. There may be several or an indefinite number of lines of connexion, or there may be but one; and a line of connexion may connect either the same pair of points or a succession of different pairs.

44. *General Principle.*—From the definition of a line of connexion it follows that the components of the velocities of a pair of connected points along their line of connexion are equal. And from this, and from the property of a rigid body, already stated in sect. 36, it follows, that the components along a line of connexion of all the points traversed by that line, whether in the driver or in the follower, are equal; and consequently, that the velocities of any pair of points traversed by a line of connexion are to each other inversely as the cosines, or directly as the secants, of the angles made by the paths of those points with the line of connexion.

The general principle stated above in different forms serves to solve every problem in which—the mode of connexion of a pair of pieces being given—it is required to find their comparative motion at a given instant, or *vice versa*.

45. *Application to a Pair of Shifting Pieces.*—In fig. 9, let  $P_1P_2$  be the line of connexion of a pair of pieces, each of which has a motion of translation or shifting. Through any point  $T$  in that line draw  $TV_1$ ,  $TV_2$ , respectively parallel to the simultaneous direction of motion of the pieces; through any other point  $A$  in the line of connexion draw a plane perpendicular to that line, cutting  $TV_1$ ,  $TV_2$  in  $V_1$ ,  $V_2$ ; then, velocity of piece 1 : velocity of piece 2 ::  $TV_1$  :  $TV_2$ . Also  $TA$  represents the equal components of the velocities of the pieces parallel to their line of connexion, and the line  $V_1V_2$  represents their velocity relatively to each other.

Fig. 9.

46. *Application to a Pair of Turning Pieces.*—Let  $a_1$ ,  $a_2$  be the angular velocities of a pair of turning pieces;  $\theta_1$ ,  $\theta_2$  the angles which their line of connexion makes with their respective planes of rotation;  $r_1$ ,  $r_2$  the common perpendiculars let fall from the line of connexion upon the respective axes of rotation of the pieces. Then the equal components, along the line of connexion, of the velocities of the points where those perpendiculars meet that line are—

$$a_1 r_1 \cos \theta_1 = a_2 r_2 \cos \theta_2 ;$$

consequently, the comparative motion of the pieces is given by the equation

$$\frac{a_2}{a_1} = \frac{r_1 \cos \theta_1}{r_2 \cos \theta_2} \dots \dots \dots (15).$$

47. *Application to a Shifting Piece and a Turning Piece.*—Let a shifting piece be connected with a turning piece, and at a given instant let  $a_1$  be the angular velocity of the turning piece,  $r_1$  the common perpendicular of its axis of rotation and the line of connexion,  $\theta_1$  the angle made by the line of connexion with the plane of rotation,  $\theta_2$  the angle made by the line of connexion with the

direction of motion of the shifting piece,  $v_2$  the linear velocity of that piece. Then

$$a_1 r_1 \cos \theta_1 = v_2 \cos \theta_2 \dots \dots \dots (16);$$

which equation expresses the comparative motion of the two pieces.

48. *Classification of Elementary Combinations in Mechanism.*—The first systematic classification of elementary combinations in mechanism was that founded by Monge, and fully developed by Lanz and Bétancourt, which has been generally received, and has been adopted in most treatises on applied mechanics. But that classification is founded on the absolute instead of the comparative motions of the pieces, and is, for that reason, defective, as Willis has pointed out in his admirable treatise *On the Principles of Mechanism*.

Willis's classification is founded, in the first place, on comparative motion, as expressed by velocity ratio and directional relation, and in the second place, on the mode of connexion of the driver and follower. He divides the elementary combinations in mechanism into three classes, of which the characters are as follows:—

Class A: Directional relation constant; velocity ratio constant.

Class B: Directional relation constant; velocity ratio varying.

Class C: Directional relation changing periodically; velocity ratio constant or varying.

Each of those classes is subdivided by Willis into five divisions, of which the characters are as follows:—

Division A: Connexion by rolling contact.

“ B: “ “ sliding contact.

“ C: “ “ wrapping connectors.

“ D: “ “ link-work.

“ E: “ “ reduplication.

In the present article the principle of Willis's classification is followed; but the arrangement is modified by taking the *mode of connexion* as the basis of the primary classification, and by removing the subject of connexion by reduplication to the section of aggregate combinations. This modified arrangement is adopted as being better suited than the original arrangement to the limits of an article in an encyclopædia; but it is not disputed that the original arrangement may be the best for a separate treatise.

49. *Rolling Contact—Smooth Wheels and Racks.*—In order that two pieces may move in *rolling contact*, it is necessary that each pair of points in the two pieces which touch each other should at the instant of contact be moving in the same direction with the same velocity. In the case of two *shifting* pieces this would involve equal and parallel velocities for all the points of each piece, so that there could be no rolling, and, in fact, the two pieces would move like one; hence, in the case of *rolling contact*, either one or both of the pieces must rotate.

The direction of motion of a point in a turning piece being perpendicular to a plane passing through its axis, the condition that each pair of points in contact with each other must move in the same direction leads to the following consequences:—

I. That, when both pieces rotate, their axes, and all their points of contact, lie in the same plane.

II. That, when one piece rotates and the other shifts, the axis of the rotating piece, and all the points of contact, lie in a plane perpendicular to the direction of motion of the shifting piece.

The condition that the velocity of each pair of points of contact must be equal leads to the following consequences:—

III. That the angular velocities of a pair of turning pieces in rolling contact must be inversely as the perpendicular distances of any pair of points of contact from the respective axes.

IV. That the linear velocity of a shifting piece in rolling contact with a turning piece is equal to the product of the angular velocity of the turning piece by the perpendicular distance from its axis to a pair of points of contact.

The *line of contact* is that line in which the points of contact are all situated. Respecting this line, the above principles III. and IV. lead to the following conclusions:—

V. That for a pair of turning pieces with parallel axes, and for a turning piece and a shifting piece, the line of contact is straight, and parallel to the axes or axis; and hence that the rolling surfaces are either plane or cylindrical (the term “cylindrical” including all surfaces generated by the motion of a straight line parallel to itself).

VI. That for a pair of turning pieces with intersecting axes the line of contact is also straight, and traverses the point of intersection of the axes; and hence that the rolling surfaces are conical, with a common apex (the term “conical” including all surfaces generated by the motion of a straight line which traverses a fixed point).

Turning pieces in rolling contact are called *smooth* or *toothless wheels*. Shifting pieces in rolling contact with turning pieces may be called *smooth* or *toothless racks*.

VII. In a pair of pieces in rolling contact every straight line traversing the line of contact is a line of connexion.

50. *Cylindrical Wheels and Smooth Racks.*—In designing cylindrical wheels and smooth racks, and determining their comparative motion, it is sufficient to consider a section of the pair of pieces made by a plane perpendicular to the axis or axes.

The points where axes intersect the plane of section are called *centres*; the point where the line of contact intersects it, the *point of contact*, or *pitch-point*; and the wheels are described as *circular*, *elliptical*, &c., according to the forms of their sections made by that plane.

When the point of contact of two wheels lies between their centres, they are said to be in *outside gearing*; when beyond their centres, in *inside gearing*, because the rolling surface of the larger wheel must in this case be turned inward or towards its centre.

From Principle III. of sect. 49 it appears that the angular velocity-ratio of a pair of wheels is the inverse ratio of the distances of the point of contact from the centres respectively.

For outside gearing that ratio is *negative*, because the wheels turn contrary ways; for inside gearing it is *positive*, because they turn the same way.

If the velocity ratio is to be constant, as in Willis's Class A, the wheels must be circular; and this is the most common form for wheels.

If the velocity ratio is to be variable, as in Willis's Class B, the figures of the wheels are a pair of *rolling curves*, subject to the condition that the distance between their *poles* (which are the centres of rotation) shall be constant.

The following is the geometrical relation which must exist between such a pair of curves. See fig. 10.

Let  $C_1, C_2$  be the poles of a pair of rolling curves;  $T_1, T_2$  any pair of points of contact;  $U_1, U_2$  any other pair of points of contact. Then, for every possible pair of points of contact, the two following equations must be simultaneously fulfilled:—

$$\begin{aligned} \text{Sum of radii, } C_1U_1 + C_2U_2 &= C_1T_1 + C_2T_2 = \text{constant}; \\ \text{arc, } T_2U_2 &= T_1U_1 \end{aligned} \quad (17).$$

A condition equivalent to the above, and necessarily connected with it, is, that at each pair of points of contact the inclinations of the curves to their radii-vectores shall be equal and contrary; or, denoting by  $r_1, r_2$  the radii-vectores at any given pair of points of contact, and  $s$  the length of the equal arcs measured from a certain fixed pair of points of contact—

$$\frac{dr_2}{ds} = -\frac{dr_1}{ds} \quad (18);$$

which is the differential equation of a pair of rolling curves whose poles are at a constant distance apart.

For full details as to rolling curves, see Willis's work, already mentioned, and Clerk Maxwell's paper on Rolling Curves in the *Transactions of the Royal Society of Edinburgh*, 1849.

A rack, to work with a circular wheel, must be straight. To work with a wheel of any other figure, its section must be a rolling curve, subject to the condition that the perpendicular distance from the pole or centre of the wheel to a straight line parallel to the direction of the motion of the rack shall be constant. Let  $r_1$  be the radius-vector of a point of contact on the wheel,  $x_2$  the ordinate from the straight line before mentioned to the corresponding point of contact on the rack. Then

$$\frac{dx_2}{ds} = -\frac{dr_1}{ds} \quad (19)$$

is the differential equation of the pair of rolling curves.

To illustrate this subject, it may be mentioned that an ellipse rotating about one focus rolls completely round in outside gearing with an equal and similar ellipse also rotating about one focus, the distance between the axes of rotation being equal to the major axis

of the ellipses, and the velocity ratio varying from  $\frac{1 + \text{eccentricity}}{1 - \text{eccentricity}}$  to  $\frac{1 - \text{eccentricity}}{1 + \text{eccentricity}}$ ; an hyperbola rotating about its further focus

rolls in inside gearing, through a limited arc, with an equal and similar hyperbola rotating about its nearer focus, the distance between the axes of rotation being equal to the axis of the hyperbolas, and the velocity ratio varying between  $\frac{\text{eccentricity} + 1}{\text{eccentricity} - 1}$  and unity; and a parabola rotating about its focus rolls with an equal and similar parabola, shifting parallel to its directrix.

51. *Conical or Bevel and Disk Wheels.*—From Principles III. and VI. of sect. 49 it appears that the angular velocities of a pair of wheels whose axes meet in a point are to each other inversely as the sines of the angles which the axes of the wheels make with the line of contact. Hence follows the following construction (figs. 11 and 12).—Let O be the apex or point of meeting of the two axes  $OC_1, OC_2$ . The angular velocity ratio being given, it is required to find the line of contact. On  $OC_1, OC_2$  take lengths  $OA_1, OA_2$ , respectively proportional to the angular velocities of the pieces on

whose axes they are taken. Complete the parallelogram  $OA_1EA_2$ ; the diagonal OET will be the line of contact required.

When the velocity ratio is variable, the line of contact will shift its position in the plane  $C_1OC_2$ , and the wheels will be cones, with eccentric or irregular bases. In every case which occurs in practice, however, the velocity ratio is constant; the line of contact is constant in position, and the rolling surfaces of the wheels are regular circular cones (when they are called *bevel wheels*); or one of a pair of wheels may have a flat disk for its rolling surface, as  $W_2$  in fig. 12, in which case it is a *disk wheel*. The rolling surfaces of actual wheels consist of frusta or zones of the complete cones or disks, as shown by  $W_1, W_2$  in figs. 11 and 12.

Fig. 11.

52. *Sliding Contact (lateral): Skew-Bevel Wheels.*—An hyperboloid of revolution is a surface resembling a sheaf or a dice box, generated by the rotation of a straight line round an axis from which it is at a constant distance, and to which it is inclined at a constant angle. If two such hyperboloids, equal or unequal, be placed in the closest possible contact, as in fig. 13, they will touch each other along one of the generating straight lines of each, which will form their line of contact, and will be inclined to the axes AG, BH in opposite directions. The axes will not be parallel, nor will they intersect each other.

Fig. 12.

The motion of two such hyperboloids, turning in contact with each other, has hitherto been classed amongst cases of rolling contact; but that classification is not strictly correct, for, although the component velocities of a pair of points of contact in a direction at right angles to the line of contact are equal, still, as the axes are neither parallel to each other nor to the line of contact, the velocities of a pair of points of contact have components along the line of contact which are unequal, and their difference constitutes a *lateral sliding*.

The directions and positions of the axes being given, and the required angular velocity ratio, the following construction serves to determine the line of contact, by whose rotation round the two axes respectively the hyperboloids are generated:—

In fig. 14, let  $B_1C_1, B_2C_2$  be the two axes;  $B_1B_2$  their common perpendicular. Through any point O in this common perpendicular draw  $OA_1$  parallel to  $B_1C_1$  and  $OA_2$  parallel to  $B_2C_2$ ; make those lines proportional to the angular velocities about the axes to which they are respectively parallel; complete the parallelogram  $OA_1EA_2$ , and draw the diagonal OE; divide  $B_1B_2$  in D into two parts, *inversely* proportional to the angular velocities about the axes which they respectively adjoin; through D parallel to OE draw DT. This will be the line of contact.

A pair of thin frusta of a pair of hyperboloids are used in practice to communicate motion between a pair of axes neither parallel nor intersecting, and are called *skew-bevel wheels*.

In skew-bevel wheels the properties of a line of connexion are not possessed by every line traversing the line of contact, but only by every line traversing the line of contact at right angles.

If the velocity ratio to be communicated were variable, the point D would alter its position, and the line DT its direction, at different periods of the motion, and the wheels would be hyperboloids of an eccentric or irregular cross-section; but forms of this kind are not used in practice.

53. *Sliding Contact (circular): Grooved Wheels.*—As the adhesion or friction between a pair of smooth wheels is seldom sufficient to prevent their slipping on each other, contrivances are used to increase their mutual hold. One of those consists in forming the rim of each wheel into a series of alternate ridges and grooves

Fig. 13.

Fig. 14.

parallel to the plane of rotation; it is applicable to cylindrical and bevel wheels, but not to skew-bevel wheels. The comparative motion of a pair of wheels so ridged and grooved is the same with that of a pair of smooth wheels in rolling contact, whose cylindrical or conical surfaces lie midway between the tops of the ridges and bottoms of the grooves, and those ideal smooth surfaces are called the *pitch-surfaces* of the wheels.

The relative motion of the faces of contact of the ridges and grooves is a *rotatory sliding* or *grinding* motion, about the line of contact of the pitch-surfaces as an instantaneous axis.

Grooved wheels have hitherto been but little used.

54. *Sliding Contact (direct): Teeth of Wheels, their Number and Pitch.*—The ordinary method of connecting a pair of wheels, or a wheel and a rack, and the only method which insures the exact maintenance of a given numerical velocity ratio, is by means of a series of alternate ridges and hollows parallel or nearly parallel to the successive lines of contact of the ideal smooth wheels whose velocity ratio would be the same with that of the toothed wheels. The ridges are called *teeth*; the hollows, *spaces*. The teeth of the driver push those of the follower before them, and in so doing sliding takes place between them in a direction across their lines of contact.

The *pitch-surfaces* of a pair of toothed wheels are the ideal smooth surfaces which would have the same comparative motion by rolling contact that the actual wheels have by the sliding contact of their teeth. The *pitch-circles* of a pair of circular toothed wheels are sections of their pitch-surfaces, made for *spur-wheels* (that is, for wheels whose axes are parallel) by a plane at right angles to the axes, and for bevel wheels by a sphere described about the common apex. For a pair of skew-bevel wheels the pitch-circles are a pair of contiguous rectangular sections of the pitch-surfaces. The *pitch-point* is the point of contact of the pitch-circles.

The pitch-surface of a wheel lies intermediate between the points of the teeth and the bottoms of the hollows between them. That part of the acting surface of a tooth which projects beyond the pitch-surface is called the *face*; that part which lies within the pitch-surface, the *flank*.

Teeth, when not otherwise specified, are understood to be made in one piece with the wheel,—the material being generally cast-iron, brass, or bronze. Separate teeth, fixed into mortises in the rim of the wheel, are called *cogs*. A *pinion* is a small toothed wheel; a *trundle* is a pinion with cylindrical *staves* for teeth.

The radius of the pitch-circle of a wheel is called the *geometrical radius*; a circle touching the ends of the teeth is called the *addendum circle*, and its radius the *real radius*; the difference between these radii, being the projection of the teeth beyond the pitch-surface, is called the *addendum*.

The distance, measured along the pitch-circle, from the face of one tooth to the face of the next, is called the *pitch*. The pitch and the number of teeth in wheels are regulated by the following principles:—

I. In wheels which rotate continuously for one revolution or more, it is obviously necessary that the *pitch should be an aliquot part of the circumference*.

In wheels which reciprocate without performing a complete revolution this condition is not necessary. Such wheels are called *sectors*.

II. In order that a pair of wheels, or a wheel and a rack, may work correctly together, it is in all cases essential that the *pitch should be the same in each*.

III. Hence, in any pair of circular wheels which work together, the numbers of teeth in a complete circumference are directly as the radii and inversely as the angular velocities.

IV. Hence also, in any pair of circular wheels which rotate continuously for one revolution or more, the ratio of the numbers of teeth and its reciprocal the angular velocity ratio must be expressible in whole numbers.

From this principle arise problems of a kind which will be referred to in treating of *Trains of Mechanism*.

V. Let  $n$ ,  $N$  be the respective numbers of teeth in a pair of wheels,  $N$  being the greater. Let  $t$ ,  $T$  be a pair of teeth in the smaller and larger wheel respectively, which at a particular instant work together. It is required to find, first, how many pairs of teeth must pass the line of contact of the pitch-surfaces before  $t$  and  $T$  work together again (let this number be called  $a$ ); and, secondly, with how many different teeth of the larger wheel the tooth  $t$  will work at different times (let this number be called  $b$ ); thirdly, with how many different teeth of the smaller wheel the tooth  $T$  will work at different times (let this be called  $c$ ).

CASE 1. If  $n$  is a divisor of  $N$ ,

$$a = N; b = \frac{N}{n}; c = 1 \quad \dots \dots (20).$$

CASE 2. If the greatest common divisor of  $N$  and  $n$  be  $d$ , a number less than  $n$ , so that  $n = md$ ,  $N = Md$ ; then

$$a = mN = Mn = Mmd; b = M; c = m \quad \dots \dots (21).$$

CASE 3. If  $N$  and  $n$  be prime to each other,

$$a = nN; b = N; c = n \quad \dots \dots (22).$$

It is considered desirable by millwrights, with a view to the preservation of the uniformity of shape of the teeth of a pair of wheels, that each given tooth in one wheel should work with as many different teeth in the other wheel as possible. They therefore study that the numbers of teeth in each pair of wheels which work together shall either be prime to each other, or shall have their greatest common divisor as small as is consistent with a velocity ratio suited for the purposes of the machine.

55. *Sliding Contact—Forms of the Teeth of Spur-wheels and Racks.*—A line of connexion of two pieces in sliding contact is a line perpendicular to their surfaces at a point where they touch. Bearing this in mind, the principle of the comparative motion of a pair of teeth belonging to a pair of spur-wheels, or to a spur-wheel and a rack, is found by applying the principles stated generally in sects. 46 and 47 to the case of parallel axes for a pair of spur-wheels, and to the case of an axis perpendicular to the direction of shifting for a wheel and a rack.

In fig. 15, let  $C_1$ ,  $C_2$  be the centres of a pair of spur-wheels;  $B_1IB_2$ ,  $B_2IB_1$  portions of their pitch-circles, touching at  $I$ , the pitch-point. Let the wheel 1 be the driver, and the wheel 2 the follower.

Let  $D_1TB_1A_1$ ,  $D_2TB_2A_2$  be the positions, at a given instant, of the acting surfaces of a pair of teeth in the driver and follower respectively, touching each other at  $T$ ; the line of connexion of those teeth is  $P_1P_2$ , perpendicular to their surfaces at  $T$ . Let  $C_1P_1$ ,  $C_2P_2$  be perpendiculars let fall from the centres of the wheels on the line of contact. Then, by sect. 46, the angular velocity-ratio is

$$\frac{\alpha_2}{\alpha_1} = \frac{C_1P_1}{C_2P_2} \quad \dots \dots (23).$$

The following principles regulate the forms of the teeth and their relative motions:—

I. The angular velocity ratio due to the sliding contact of the teeth will be the same with that due to the rolling contact of the pitch-circles, if the line of connexion of the teeth cuts the line of centres at the pitch-point.

For, let  $P_1P_2$  cut the line of centres at  $I$ ; then, by similar triangles,

$$\alpha_1 : \alpha_2 :: C_2P_2 : C_1P_1 :: IC_2 : IC_1 \quad \dots \dots (24);$$

which is also the angular velocity ratio due to the rolling contact of the circles  $B_1IB_2$ ,  $B_2IB_1$ .

This principle determines the *forms* of all teeth of spur-wheels. It also determines the forms of the teeth of straight racks, if one of the centres be removed, and a straight line  $EIE'$ , parallel to the direction of motion of the rack, and perpendicular to  $C_1C_2$ , be substituted for a pitch-circle.

II. The component of the velocity of the point of contact of the teeth  $T$  along the line of connexion is

$$\alpha_1 \cdot C_1P_1 = \alpha_2 \cdot C_2P_2 \quad \dots \dots (25).$$

III. The relative velocity perpendicular to  $P_1P_2$  of the teeth at their point of contact,—that is, their *velocity of sliding* on each other,—is found by supposing one of the wheels, such as 1, to be fixed, the line of centres  $C_1C_2$  to rotate backwards round  $C_1$  with the angular velocity  $\alpha_1$ , and the wheel 2 to rotate round  $C_2$  as before, with the angular velocity  $\alpha_2$  relatively to the line of centres  $C_1C_2$ , so as to have the same motion as if its pitch-circle *rolled* on the pitch-circle of the first wheel. Thus the *relative* motion of the wheels is unchanged; but 1 is considered as fixed, and 2 has the *total motion* given by the principles of sects. 37 and 38,—that is, a rotation about the instantaneous axis  $I$ , with the angular velocity  $\alpha_1 + \alpha_2$ . Hence the *velocity of sliding* is that due to this rotation about  $I$ , with the radius  $IT$ ; that is to say, its value is

$$(\alpha_1 + \alpha_2) \cdot IT \quad \dots \dots (26);$$

so that it is greater the farther the point of contact is from the line of centres; and at the instant when that point passes the line of centres, and coincides with the *pitch-point*, the velocity of sliding is null, and the action of the teeth is, for the instant, that of rolling contact.

IV. The *path of contact* is the line traversing the various positions of the point  $T$ . If the line of connexion preserves always the same

Fig. 15.

position, the path of contact coincides with it, and is straight; in other cases the path of contact is curved.

It is divided by the pitch-point I into two parts,—the *arc or line of approach* described by T in approaching the line of centres, and the *arc or line of recess* described by T after having passed the line of centres.

During the *approach*, the flank  $D_1B_1$  of the driving tooth drives the face  $D_2B_2$  of the following tooth, and the teeth are sliding *towards* each other. During the *recess* (in which the position of the teeth is exemplified in the figure by curves marked with accented letters), the face  $B_1A_1$  of the driving tooth drives the flank  $B_2A_2$  of the following tooth, and the teeth are sliding *from* each other.

The path of contact is bounded where the approach commences by the addendum-circle of the follower, and where the recess terminates by the addendum-circle of the driver. The length of the path of contact should be such that there shall always be at least one pair of teeth in contact; and it is better still to make it so long that there shall always be at least two pairs of teeth in contact.

V. The *obliquity* of the action of the teeth is the angle  $EIT = IC_1P_1 = IC_2P_2$ .

In practice it is found desirable that the mean value of the obliquity of action during the contact of teeth should not exceed  $15^\circ$ , nor the maximum value  $30^\circ$ .

It is unnecessary to give separate figures and demonstrations for inside gearing. The only modification required in the formulæ is, that in equation 26 the *difference* of the angular velocities should be substituted for their *sum*.

56. *Involute Teeth*.—The simplest form of tooth which fulfils the conditions of sect. 55 is obtained in the following manner (see fig. 16). Let  $C_1, C_2$  be the centres of two wheels,  $B_1IB_2, B_2IB_1$  their pitch-circles, I the pitch-point; let the obliquity of action of the teeth be constant, so that the same straight line  $P_1IP_2$  shall represent at once the constant line of connexion of teeth and the path of contact. Draw  $C_1P_1, C_2P_2$  perpendicular to  $P_1IP_2$ , and with those lines as radii describe about the centres of the wheels the circles  $D_1D'_1, D_2D'_2$ , called *base-circles*. It is evident that the radii of the base-circles bear to each other the same proportions as the radii of the pitch-circles, and also that

$$\left. \begin{aligned} C_1P_1 &= IC_1 \cdot \cos \text{obliquity} \\ C_2P_2 &= IC_2 \cdot \cos \text{obliquity} \end{aligned} \right\} \dots \dots (27).$$

(The obliquity which is found to answer best in practice is about  $14\frac{1}{2}^\circ$ ; its cosine is about  $\frac{3}{4}$ , and its sine about  $\frac{1}{4}$ . These values, though not absolutely exact, are near enough to the truth for practical purposes.)

Suppose the base-circles to be a pair of circular pulleys connected by means of a cord whose course from pulley to pulley is  $P_1IP_2$ . As the line of connexion of those pulleys is the same with that of the proposed teeth, they will rotate with the required velocity ratio. Now, suppose a tracing-point T to be fixed to the cord, so as to be carried along the path of contact  $P_1IP_2$ , that point will trace on a plane rotating along with the wheel 1 part of the involute of the base-circle  $D_1D'_1$ , and on a plane rotating along with the wheel 2 part of the involute of the base-circle  $D_2D'_2$ ; and the two curves so traced will always touch each other in the required point of contact T, and will therefore fulfil the condition required by Principle I. of sect. 55.

Consequently, one of the forms suitable for the teeth of wheels is the involute of a circle; and the obliquity of the action of such teeth is the angle whose cosine is the ratio of the radius of their base-circle to that of the pitch-circle of the wheel.

All involute teeth of the same pitch work smoothly together.

To find the length of the path of contact on either side of the pitch-point I, it is to be observed that the distance between the fronts of two successive teeth, as measured along  $P_1IP_2$ , is less than the pitch in the ratio of  $\cos \text{obliquity} : 1$ ; and consequently that, if distances equal to the pitch be marked off either way from I towards  $P_1$  and  $P_2$  respectively, as the extremities of the path of contact, and if, according to Principle IV. of sect. 55, the addendum-circles be described through the points so found, there will always be at least two pairs of teeth in action at once. In practice it is usual to make the path of contact somewhat longer, viz., about  $2\frac{1}{2}$  times the pitch; and with this length of path, and the obliquity already mentioned of  $14\frac{1}{2}^\circ$ , the addendum is about  $\frac{1}{10}$ ths of the pitch.

Fig. 16.

The teeth of a *rack*, to work correctly with wheels having involute teeth, should have plane surfaces perpendicular to the line of connexion, and consequently making with the direction of motion of the rack angles equal to the complement of the obliquity of action.

57. *Teeth for a given Path of Contact—Mr Sang's Method*.—In the preceding section the form of the teeth is found by assuming a figure for the path of contact, viz., the straight line. Any other convenient figure may be assumed for the path of contact, and the corresponding forms of the teeth found by determining what curves a point T, moving along the assumed path of contact, will trace on two disks rotating round the centres of the wheels with angular velocities bearing that relation to the component velocity of T along TI, which is given by Principle II. of sect. 55, and by equation 25. This method of finding the forms of the teeth of wheels forms the subject of an elaborate and most interesting treatise by Mr Edward Sang.

All wheels having teeth of the same pitch, traced from the same path of contact, work correctly together, and are said to belong to the *same set*.

58. *Teeth traced by Rolling Curves*.—If any curve R (fig. 17) be rolled on the inside of the pitch-circle BB of a wheel, it appears, from sect. 37, that the instantaneous axis of the rolling curve at any instant will be at the point I, where it touches the pitch-circle for the moment, and that consequently the line AT, traced by a tracing-point T, fixed to the rolling curve upon the plane of the wheel, will be everywhere perpendicular to the straight line TI; so that the traced curve AT will be suitable for the flank of a tooth, in which T is the point of contact corresponding to the position I of the pitch-point. If the same rolling curve R, with the same tracing-point T, be rolled on the *outside* of any other pitch-circle, it will have the *face* of a tooth suitable to work with the *flank* AT.

In like manner, if either the same or any other rolling curve R' be rolled the opposite way, on the *outside* of the pitch-circle BB, so that the tracing-point T' shall start from A, it will trace the *face* AT' of a tooth suitable to work with a *flank* traced by rolling the same curve R' with the same tracing-point T' *inside* any other pitch-circle.

The figure of the *path of contact* is that traced on a fixed plane by the tracing-point, when the rolling curve is rotated in such a manner as always to touch a fixed straight line EIE (or E'I'E', as the case may be) at a fixed point I (or I').

If the same rolling curve and tracing point be used to trace both the faces and the flanks of the teeth of a number of wheels of different sizes but of the same pitch, all those wheels will work correctly together, and will form a *set*. The teeth of a *rack*, of the same set, are traced by rolling the rolling curve on both sides of a straight line.

The teeth of wheels of any figure, as well as of circular wheels, may be traced by rolling curves on their pitch-surfaces; and all teeth of the same pitch, traced by the same rolling curve with the same tracing-point, will work together correctly if their pitch-surfaces are in rolling contact.

59. *Epicycloidal Teeth*.—The most convenient rolling curve is the circle. The path of contact which it traces is identical with itself; and the flanks of the teeth are internal and their faces external epicycloids for wheels, and both flanks and faces are cycloids for a rack.

For a pitch-circle of twice the radius of the rolling or *describing* circle (as it is called) the internal epicycloid is a straight line, being, in fact, a diameter of the pitch circle, so that the flanks of the teeth for such a pitch-circle are planes radiating from the axis. For a smaller pitch-circle the flanks would be convex and *incurred* or *under-cut*, which would be inconvenient; therefore the smallest wheel of a set should have its pitch-circle of twice the radius of the describing circle, so that the flanks may be either straight or concave.

In fig. 18, let BB' be part of the pitch-circle of a wheel with epicycloidal teeth; CIO' the line of centres; I the pitch-point; EIE'

Fig. 17.

Fig. 18.

a straight tangent to the pitch-circle at that point;  $R$  the internal and  $R'$  the equal external describing circles, so placed as to touch the pitch-circle and each other at  $I$ . Let  $DID'$  be the path of contact, consisting of the arc of approach  $DI$  and the arc of recess  $ID'$ . In order that there may always be at least two pairs of teeth in action, each of those arcs should be equal to the pitch.

The obliquity of the action in passing the line of centres is nothing; the maximum obliquity is the angle  $EID = E'ID'$ ; and the mean obliquity is one-half of that angle.

It appears from experience that the mean obliquity should not exceed  $15^\circ$ ; therefore the maximum obliquity should be about  $30^\circ$ ; therefore the equal arcs  $DI$  and  $ID'$  should each be one-sixth of a circumference; therefore the circumference of the describing circle should be *six times the pitch*.

It follows that the smallest pinion of a set in which pinion the flanks are straight should have twelve teeth.

60. *Nearly Epicycloidal Teeth—Willis's Method.*—To facilitate the drawing of epicycloidal teeth in practice, Willis has shown how to approximate to their figure by means of two circular arcs,—one concave, for the flank, and the other convex, for the face,—and each having for its radius the *mean* radius of curvature of the epicycloidal arc. Willis's formulæ are founded on the following properties of epicycloids:—

Let  $R$  be the radius of the pitch-circle;  $r$  that of the describing circle;  $\theta$  the angle made by the normal  $TI$  to the epicycloid at a given point  $T$ , with a tangent to the circle at  $I$ ; that is, the obliquity of the action at  $T$ .

Then the radius of curvature of the epicycloid at  $T$  is—

$$\left. \begin{array}{l} \text{For an internal epicycloid, } \rho = 4r \sin \theta \frac{R-r}{R-2r} \\ \text{For an external epicycloid, } \rho' = 4r \sin \theta \frac{R+r}{R+2r} \end{array} \right\} \dots (28).$$

Also, to find the position of the centres of curvature relatively to the pitch-circle, we have, denoting the chord of the describing circle  $TI$  by  $c$ ,  $c = 2r \sin \theta$ ; and therefore

$$\left. \begin{array}{l} \text{For the flank, } \rho - c = 2r \sin \theta \frac{R}{R-2r} \\ \text{For the face, } \rho' - c = 2r \sin \theta \frac{R}{R+2r} \end{array} \right\} \dots (29).$$

For the proportions approved of by Willis,  $\sin \theta = \frac{1}{4}$  nearly;  $r = p$  (the pitch) nearly;  $c = \frac{1}{2}p$  nearly; and, if  $N$  be the number of teeth in the wheel,  $\frac{r}{R} = \frac{6}{N}$  nearly; therefore, approximately,

$$\left. \begin{array}{l} \rho - c = \frac{p}{2} \cdot \frac{N}{N-12} \\ \rho' - c = \frac{p}{2} \cdot \frac{N}{N+12} \end{array} \right\} \dots (30).$$

Hence the following construction (fig. 19). Let  $BB'$  be part of the pitch-circle, and  $a$  the point where a tooth is to cross it. Set off  $ab = ac = \frac{1}{2}p$ . Draw radii  $ba$ ,  $ca$ ; draw  $fb$ ,  $cg$ , making angles of  $75\frac{1}{2}^\circ$  with those radii. Make  $bf = \rho - c$ ,  $cg = \rho' - c$ . From  $f$ , with the radius  $fa$ , draw the circular arc  $ah$ ; from  $g$ , with the radius  $ga$ , draw the circular arc  $ak$ . Then  $ah$  is the face and  $ak$  the flank of the tooth required.

To facilitate the application of this rule, Willis published tables of  $\rho - c$  and  $\rho' - c$ , and invented an instrument called the "odontograph."

61. *Trundles and Pin-Wheels.*—If a wheel or trundle have cylindrical pins or staves for teeth, the faces of the teeth of a wheel suitable for driving it are described by first tracing external epicycloids, by rolling the pitch-circle of the pin-wheel or trundle on the pitch-circle of the driving-wheel, with the centre of a staff for a tracing-point, and then drawing curves parallel to, and within the epicycloids, at a distance from them equal to the radius of a staff. Trundles having only six staves will work with large wheels.

62. *Backs of Teeth and Spaces.*—Toothed wheels being in general intended to rotate either way, the *backs* of the teeth are made similar to the fronts. The *space* between two teeth, measured on the pitch-circle, is made about  $\frac{1}{4}$ th part wider than the thickness of the tooth on the pitch-circle; that is to say,

$$\left. \begin{array}{l} \text{Thickness of tooth} = \frac{1}{4} \text{ pitch;} \\ \text{Width of space} = \frac{1}{4} \text{ pitch.} \end{array} \right\}$$

The difference of  $\frac{1}{4}$ th of the pitch is called the *back-lash*. The clearance allowed between the points of teeth and the bottoms of the spaces between the teeth of the other wheel is about  $\frac{1}{16}$ th of the pitch.

63. *Stepped and Helical Teeth.*—Hooke invented the making of the fronts of teeth in a series of steps with a view to increase the smoothness of action. A wheel thus formed resembles in shape a series of equal and similar toothed disks placed side by side, with the teeth of each a little behind those of the preceding disk. He also invented, with the same object, teeth whose fronts, instead of being parallel to the line of contact of the pitch-circles, cross it obliquely, so as to be of a screw-like or helical form. In wheel-work of this kind the contact of each pair of teeth commences at the foremost end of the helical front, and terminates at the aftermost end; and the helix is of such a pitch that the contact of one pair of teeth shall not terminate until that of the next pair has commenced.

Stepped and helical teeth have the desired effect of increasing the smoothness of motion, but they require more difficult and expensive workmanship than common teeth; and helical teeth are, besides, open to the objection that they exert a laterally oblique pressure, which tends to increase resistance, and unduly strain the machinery.

64. *Teeth of Bevel-Wheels.*—The acting surfaces of the teeth of bevel-wheels are of the conical kind, generated by the motion of a line passing through the common apex of the pitch-cones, while its extremity is carried round the outlines of the cross section of the teeth made by a sphere described about that apex.

The operations of describing the exact figures of the teeth of bevel-wheels, whether by involutes or by rolling curves, are in every respect analogous to those for describing the figures of the teeth of spur-wheels, except that in the case of bevel-wheels all those operations are to be performed on the surface of a sphere described about the apex instead of on a plane, substituting *poles* for *centres*, and *great circles* for *straight lines*.

In consideration of the practical difficulty, especially in the case of large wheels, of obtaining an accurate spherical surface, and of drawing upon it when obtained, the following approximate method, proposed originally by Tredgold, is generally used:—

Let  $O$  (fig. 20) be the common apex of a pair of bevel-wheels;  $OB_1I$ ,  $OB_2I$  their pitch cones;  $OC_1$ ,  $OC_2$  their axes;  $OI$  their line of contact. Perpendicular to  $OI$  draw  $A_1IA_2$ , cutting the axes in  $A_1$ ,  $A_2$ ; make the outer rims of the patterns and of the wheels portions of the cones  $A_1B_1I$ ,  $A_2B_2I$ , of which the narrow zones occupied by the teeth will be sufficiently near to a spherical surface described about  $O$  for practical purposes. To find the figures of the teeth, draw on a flat surface circular arcs  $ID_1$ ,  $ID_2$ , with the radii  $A_1I$ ,  $A_2I$ ; those arcs will be the *developments* of arcs of the pitch-circles  $B_1I$ ,  $B_2I$ , when the conical surfaces  $A_1B_1I$ ,  $A_2B_2I$  are spread out flat. Describe the figures of teeth for the developed arcs as for a pair of spur-wheels; then wrap the developed arcs on the cones, so as to make them coincide with the pitch-circles, and trace the teeth on the conical surfaces.

Fig. 20.

65. *Teeth of Skew-Bevel Wheels.*—The crests of the teeth of a skew-bevel wheel are parallel to the generating straight line of the hyperboloidal pitch-surface; and the transverse sections of the teeth at a given pitch-circle are similar to those of the teeth of a bevel-wheel whose pitch-surface is a cone touching the hyperboloidal surface at the given circle.

66. *Cams.*—A *cam* is a single tooth, either rotating continuously or oscillating, and driving a sliding or turning piece either constantly or at intervals. All the principles which have been stated in sect. 55 as being applicable to teeth are applicable to cams; but in designing cams it is not usual to determine or take into consideration the form of the ideal pitch-surface, which would give the same comparative motion by rolling contact that the cam gives by sliding contact.

67. *Screws.*—The figure of a screw is that of a convex or concave cylinder, with one or more helical projections, called *threads*, winding round it. Convex and concave screws are distinguished technically by the respective names of *male* and *female*; a short concave screw is called a *nut*; and when a *screw* is spoken of without qualification a *convex* screw is usually understood.

The relation between the *advance* and the *rotation*, which compose the motion of a screw working in contact with a fixed screw or helical guide, has already been demonstrated in sect. 41; and the same relation exists between the magnitudes of the rotation of a screw about a fixed axis and the advance of a shifting nut in which it rotates. The advance of the nut takes place in the opposite direction to that of the advance of the screw in the case in which the nut is fixed. The *pitch* or *axial pitch* of a screw has the meaning assigned to it in that section, viz. the distance, measured

parallel to the axis, between the corresponding points in two successive turns of the *same thread*. If, therefore, the screw has several equidistant threads, the true pitch is equal to the *divided axial pitch*, as measured between two adjacent threads, multiplied by the number of threads.

If a helix be described round the screw, crossing each turn of the thread at right angles, the distance between two corresponding points on two successive turns of the same thread, measured along this *normal helix*, may be called the *normal pitch*; and when the screw has more than one thread the normal pitch from thread to thread may be called the *normal divided pitch*.

The distance from thread to thread, measured on a circle described about the axis of the screw, called the *pitch-circle*, may be called the *circumferential pitch*; for a screw of one thread it is one circumference; for a screw of  $n$  threads,  $\frac{\text{one circumference}}{n}$ .

Let  $r$  denote the radius of the pitch circle;

$n$  the number of threads;

$\theta$  the obliquity of the threads to the pitch circle, and of the normal helix to the axis;

$$\left. \begin{aligned} \frac{P_a}{n} = p_a \end{aligned} \right\} \begin{aligned} &\text{the axial} \\ &\left\{ \begin{aligned} &\text{pitch,} \\ &\text{divided pitch;} \end{aligned} \right. \end{aligned}$$

$$\left. \begin{aligned} \frac{P_n}{n} = p_n \end{aligned} \right\} \begin{aligned} &\text{the normal} \\ &\left\{ \begin{aligned} &\text{pitch,} \\ &\text{divided pitch;} \end{aligned} \right. \end{aligned}$$

$$P_c \text{ the circumferential pitch;} ;$$

$$\text{then} \quad \left. \begin{aligned} p_c &= p_a \cot \theta = p_n \cos \theta = \frac{2\pi r}{n} \\ p_a &= p_n \sec \theta = p_c \tan \theta = \frac{2\pi r \tan \theta}{n} \\ p_n &= p_c \sin \theta = p_a \cos \theta = \frac{2\pi r \sin \theta}{n} \end{aligned} \right\} \quad \dots (31).$$

If a screw rotates, the number of threads which pass a fixed point in one revolution is the number of threads in the screw.

A pair of convex screws, each rotating about its axis, are used as an elementary combination to transmit motion by the sliding contact of their threads. Such screws are commonly called *endless screws*. At the point of contact of the screws their threads must be parallel; and their line of connexion is the common perpendicular to the acting surfaces of the threads at their point of contact. Hence the following principles:—

I. If the screws are both right-handed or both left-handed, the angle between the directions of their axes is the sum of their obliquities; if one is right-handed and the other left-handed, that angle is the difference of their obliquities.

II. The normal pitch for a screw of one thread, and the normal divided pitch for a screw of more than one thread, must be the same in each screw.

III. The angular velocities of the screws are inversely as their numbers of threads.

Hooke's wheels with oblique or helical teeth are in fact screws of many threads, and of large diameters as compared with their lengths.

The ordinary position of a pair of endless screws is with their axes at right angles to each other. When one is of considerably greater diameter than the other, the larger is commonly called in practice a *wheel*, the name *screw* being applied to the smaller only; but they are nevertheless both screws in fact.

To make the teeth of a pair of endless screws fit correctly and work smoothly, a hardened steel screw is made of the figure of the smaller screw, with its thread or threads notched so as to form a cutting tool; the larger screw, or "wheel," is cast approximately of the required figure; the larger screw and the steel screw are fitted up in their proper relative position, and made to rotate in contact with each other by turning the steel screw, which cuts the threads of the larger screw to their true figure.

68. *Coupling of Parallel Axes—Oldham's Coupling.*—A coupling is a mode of connecting a pair of shafts so that they shall rotate in the same direction with the same mean angular velocity. If the axes of the shafts are in the same straight line, the coupling consists in so connecting their contiguous ends that they shall rotate as one piece; but if the axes are not in the same straight line combinations of mechanism are required. A coupling for parallel shafts which acts by *sliding contact* was invented by Oldham, and is represented in fig. 21.  $C_1, C_2$  are the axes of the two parallel shafts;  $D_1, D_2$  two disks facing each other, fixed on the

Fig. 21.

ends of the two shafts respectively;  $E_1, E_2$  a bar sliding in a diametral groove in the face of  $D_1$ ;  $E_2, E_2$  a bar sliding in a diametral groove in the face of  $D_2$ ; those bars are fixed together at A, so as to form a rigid cross. The angular velocities of the two disks and of the cross are all equal at every instant; the middle point of the cross, at A, revolves in the dotted circle described upon the line of centres  $C_1, C_2$  as a diameter twice for each turn of the disks and cross; the instantaneous axis of rotation of the cross at any instant is at I, the point in the circle  $C_1, C_2$  diametrically opposite to A.

Oldham's coupling may be used with advantage where the axes of the shafts are intended to be as nearly in the same straight line as is possible, but where there is some doubt as to the practicability or permanency of their exact continuity.

69. *Wrapping Connectors—Belts, Cords, and Chains.*—Flat belts of leather or of gutta percha, round cords of catgut, hemp, or other material, and metal chains are used as wrapping connectors to transmit rotatory motion between pairs of pulleys and drums.

*Belts* (the most frequently used of all wrapping connectors) require nearly cylindrical pulleys. A belt tends to move towards that part of a pulley whose radius is greatest; pulleys for belts, therefore, are slightly swelled in the middle, in order that the belt may remain on a pulley, unless forcibly shifted. A belt when in motion is shifted off a pulley, or from one pulley on to another of equal size alongside of it, by pressing against that part of the belt which is moving *towards* the pulley.

*Cords* require either cylindrical drums with ledges or grooved pulleys.

*Chains* require pulleys or drums, grooved, notched, and toothed, so as to fit the links of the chain.

Wrapping connectors for communicating continuous motion are endless.

Wrapping connectors for communicating reciprocating motion have usually their ends made fast to the pulleys or drums which they connect, and which in this case may be sectors.

The line of connexion of two pieces connected by a wrapping connector is the centre line of the belt, cord, or chain; and the comparative motions of the pieces are determined by the principles of sect. 46 if both pieces turn, and of sect. 47 if one turns and the other shifts, in which latter case the motion must be reciprocating.

The *pitch-line* of a pulley or drum is a curve to which the line of connexion is always a tangent; that is to say, it is a curve parallel to the acting surface of the pulley or drum, and distant from it by half the thickness of the wrapping connector.

Pulleys and drums for communicating a constant velocity ratio are circular. The *effective radius*, or radius of the pitch-circle of a circular pulley or drum, is equal to the real radius added to half the thickness of the connector. The angular velocities of a pair of connected circular pulleys or drums are inversely as the effective radii.

A *crossed belt*, as in fig. 22, A, reverses the direction of the rotation communicated; an *uncrossed belt*, as in fig. 22, B, preserves that direction.

The *length L* of an endless belt connecting a pair of pulleys whose effective radii are  $r_1, r_2$ , with parallel axes whose distance apart is  $C$ , is given by the following formulæ, in each of which the first term, containing the radical, expresses the length of the straight parts of the belt, and the remainder of the formula the length of the curved parts.

For a crossed belt,—

$$L = 2\sqrt{C^2 - (r_1 + r_2)^2} + (r_1 + r_2) \left( \pi - 2 \sin^{-1} \frac{r_1 + r_2}{C} \right) \quad (32, A);$$

and for an uncrossed belt,—

$$L = 2\sqrt{C^2 - (r_1 - r_2)^2} + \pi(r_1 + r_2) + 2(r_1 - r_2) \sin^{-1} \frac{r_1 - r_2}{C} \quad (32, B);$$

in which  $r_1$  is the greater radius, and  $r_2$  the less.

When the axes of a pair of pulleys are not parallel, the pulleys should be so placed that the part of the belt which is *approaching* each pulley shall be in the plane of the pulley.

70. *Speed-Cones* (see fig. 23).—A pair of speed-cones is a contrivance for varying and adjusting the velocity ratio communicated between a pair of parallel shafts by means of a belt. The speed-cones are either continuous cones or conoids, as A, B, whose velocity ratio can be varied gradually while they are in motion by shifting the belt, or sets of pulleys whose radii vary by steps, as C, D, in which case the velocity ratio can be changed by shifting the belt from one pair of pulleys to another.

Fig. 22.

In order that the belt may fit accurately in every possible position on a pair of speed-cones, the quantity  $L$  must be constant, in equations 32, A, or 32, B, according as the belt is crossed or uncrossed.

For a *crossed* belt, as in A and C, fig. 23,  $L$  depends solely on  $c$  and on  $r_1 + r_2$ . Now  $c$  is constant because the axes are parallel; therefore the *sum of the radii* of the pitch-circles connected in every position of the belt is to be constant. That condition is fulfilled by a pair of continuous cones generated by the revolution of two straight lines inclined opposite ways to their respective axes at equal angles.

Fig. 23.

For an uncrossed belt, the quantity  $L$  in equation 32, B is to be made constant. The exact fulfilment of this condition requires the solution of a transcendental equation; but it may be fulfilled with accuracy sufficient for practical purposes by using, instead of 32, B, the following *approximate* equation:—

$$L \text{ nearly} = 2c + \pi(r_1 + r_2) + \frac{(r_1 - r_2)^2}{c} \quad (33).$$

The following is the most convenient practical rule for the application of this equation:—

Let the speed-cones be equal and similar conoids, as in B, fig. 23, but with their large and small ends turned opposite ways. Let  $r_1$  be the radius of the large end of each,  $r_2$  that of the small end,  $r_0$  that of the middle; and let  $v$  be the *sagitta*, measured perpendicular to the axes, of the arc by whose revolution each of the conoids is generated, or, in other words, the *bulging* of the conoids in the middle of their length. Then

$$v = r_0 - \frac{r_1 + r_2}{2} = \frac{(r_1 - r_2)^2}{2\pi c} \quad (34).$$

$2\pi = 6.2832$ ; but 6 may be used in most practical cases without sensible error.

The radii at the middle and end being thus determined, make the generating curve an arc either of a circle or of a parabola.

71. *Linkwork in General.*—The pieces which are connected by linkwork, if they rotate or oscillate, are usually called *cranks*, *beams*, and *levers*. The *link* by which they are connected is a rigid rod or bar, which may be straight or of any other figure; the straight figure, being the most favourable to strength, is always used when there is no special reason to the contrary. The link is known by various names under various circumstances, such as *coupling-rod*, *connecting-rod*, *crank-rod*, *eccentric-rod*, &c. It is attached to the pieces which it connects by two pins, about which it is free to turn. The effect of the link is to maintain the distance between the axes of those pins invariable; hence the common perpendicular of the axes of the pins is the *line of connexion*, and its extremities may be called the *connected points*. In a turning piece, the perpendicular let fall from its connected point upon its axis of rotation is the *arm* or *crank-arm*.

The axes of rotation of a pair of turning pieces connected by a link are almost always parallel, and perpendicular to the line of connexion; in which case the angular velocity ratio at any instant is the reciprocal of the ratio of the common perpendiculars let fall from the line of connexion upon the respective axes of rotation.

If at any instant the direction of one of the crank-arms coincides with the line of connexion, the common perpendicular of the line of connexion and the axis of that crank-arm vanishes, and the directional relation of the motions becomes indeterminate. The position of the connected point of the crank-arm in question at such an instant is called a *dead-point*. The velocity of the other connected point at such an instant is null, unless it also reaches a dead-point at the same instant, so that the line of connexion is in the plane of the two axes of rotation, in which case the velocity ratio is indeterminate. Examples of dead-points, and of the means of preventing the inconvenience which they tend to occasion, will appear in the sequel.

72. *Coupling of Parallel Axes.*—Two or more parallel shafts (such as those of a locomotive engine, with two or more pairs of driving wheels) are made to rotate with constantly equal angular velocities by having equal cranks, which are maintained parallel by a coupling-rod of such a length that the line of connexion is equal to the distance between the axes. The cranks pass their dead-points simultaneously. To obviate the unsteadiness of motion which this tends to cause, the shafts are provided with a second set of cranks at right angles to the first, connected by means of a similar coupling-rod, so that one set of cranks pass their dead-points at the instant when the other set are farthest from theirs.

73. *Comparative Motion of Connected Points.*—As the link is a rigid body, it is obvious that its action in communicating motion may be determined by finding the comparative motion of the connected points, according to the principles laid down in §§ 71, 78, pp. 690, 692, and this is often the most convenient method of proceeding.

If a connected point belongs to a turning piece, the direction of its motion at a given instant is perpendicular to the plane containing the axis and crank-arm of the piece. If a connected point belongs to a shifting piece, the direction of its motion at any instant is given, and a plane can be drawn perpendicular to that direction.

The line of intersection of the planes perpendicular to the paths of the two connected points at a given instant is the *instantaneous axis of the link* at that instant; and the *velocities of the connected points are directly as their distances from that axis*.

In drawing on a plane surface, the two planes perpendicular to the paths of the connected points are represented by two lines (being their sections by a plane normal to them), and the instantaneous axis by a point (fig. 24); and, should the length of the two lines render it impracticable to produce them until they actually intersect, the velocity ratio of the connected points may be found by the principle that it is equal to the ratio of the segments which a line parallel to the line of connexion cuts off from any two lines drawn from a given point, perpendicular respectively to the paths of the connected points.

To illustrate this by one example. Let  $C_1$  be the axis, and  $T_1$  the connected point of the beam of a steam-engine;  $T_1T_2$  the connecting or crank-rod;  $T_2$  the other connected point, and the centre of the crank-pin;  $C_2$  the axis of the crank and its shaft. Let  $v_1$  denote the velocity of  $T_1$  at any given instant;  $v_2$  that of  $T_2$ . To find the ratio of these velocities, produce  $C_1T_1$ ,  $C_2T_2$ , till they intersect in  $K$ ;  $K$  is the instantaneous axis of the connecting rod, and the velocity ratio is

$$v_1 : v_2 :: KT_1 : KT_2. \quad (35).$$

Should  $K$  be inconveniently far off, draw any triangle with its sides respectively parallel to  $C_1T_1$ ,  $C_2T_2$ , and  $T_1T_2$ ; the ratio of the two sides first mentioned will be the velocity ratio required. For example, draw  $C_2A$  parallel to  $C_1T_1$ , cutting  $T_1T_2$  in  $A$ ; then

$$v_1 : v_2 :: C_2A : C_2T_2 \quad (36).$$

74. *Eccentric.*—An eccentric circular disk fixed on a shaft, and used to give a reciprocating motion to a rod, is in effect a crank-pin of sufficiently large diameter to surround the shaft, and so to avoid the weakening of the shaft which would arise from bending it so as to form an ordinary crank. The centre of the eccentric is its connected point; and its eccentricity, or the distance from that centre to the axis of the shaft, is its crank-arm.

An eccentric may be made capable of having its eccentricity altered by means of an adjusting screw, so as to vary the extent of the reciprocating motion which it communicates.

75. *Reciprocating Pieces—Stroke—Dead-Points.*—The distance between the extremities of the path of the connected point in a reciprocating piece (such as the piston of a steam-engine) is called the *stroke* or *length of stroke* of that piece. When it is connected with a continuously turning piece (such as the crank of a steam-engine) the ends of the stroke of the reciprocating piece correspond to the *dead-points* of the path of the connected point of the turning piece, where the line of connexion is continuous with or coincides with the crank-arm.

Let  $S$  be the length of stroke of the reciprocating piece,  $L$  the length of the line of connexion, and  $R$  the crank-arm of the continuously turning piece. Then, if the two ends of the stroke be in one straight line with the axis of the crank,

$$S = 2R \quad (37);$$

and if these ends be not in one straight line with that axis, then  $S$ ,  $L - R$ , and  $L + R$ , are the three sides of a triangle, having the angle opposite  $S$  at that axis; so that, if  $\theta$  be the supplement of the arc between the dead-points,

$$\left. \begin{aligned} S^2 &= 2(L^2 + R^2) - 2(L^2 - R^2)\cos\theta \\ \cos\theta &= \frac{2L^2 + 2R^2 - S^2}{2(L^2 - R^2)} \end{aligned} \right\} \quad (38).$$

76. *Coupling of Intersecting Axes—Hooke's Universal Joint.*—Intersecting axes are coupled by a contrivance of Hooke's, known as the "universal joint," which belongs to the class of linkwork (see fig. 25). Let  $O$  be the point of intersection of the axes  $OC_1$ ,  $OC_2$ , and  $\theta$  their angle of inclination to each other. The pair of shafts  $C_1$ ,  $C_2$  terminate in a pair of forks  $F_1$ ,  $F_2$  in bearings at the extremities.

ties of which turn the gudgeons at the ends of the arms of a rectangular cross, having its centre at O. This cross is the link; the connected points are the centres of the bearings  $F_1$ ,  $F_2$ . At each instant each of those points moves at right angles to the central plane of its shaft and fork; therefore the line of intersection of the central planes of the two forks at any instant is the instantaneous axis of the cross, and the velocity ratio of the points  $F_1$ ,  $F_2$  (which, as the forks are equal, is also the angular velocity ratio of the shafts) is equal to the ratio of the distances of those points from that instantaneous axis. The mean value of that velocity ratio is that of equality, for each successive quarter-turn is made by both shafts in the same time; but its actual value fluctuates between the limits—

Fig. 25.

$$\left. \begin{aligned} \frac{a_2}{a_1} &= \frac{1}{\cos \theta} \text{ when } F_1 \text{ is the plane } OC_1C_2 \\ \frac{a_2}{a_1} &= \cos \theta \text{ when } F_2 \text{ is in that plane} \end{aligned} \right\} \dots (39).$$

Its value at intermediate instants is given by the following equations:—let  $\phi_1$ ,  $\phi_2$  be the angles respectively made by the central planes of the forks and shafts with the plane  $OC_1C_2$  at a given instant; then

$$\left. \begin{aligned} \cos \theta &= \tan \phi_1 \tan \phi_2 \\ \frac{a_2}{a_1} &= -\frac{d\phi_2}{d\phi_1} = \frac{\tan \phi_1 + \cot \phi_1}{\tan \phi_2 + \cot \phi_2} \end{aligned} \right\} \dots (40).$$

77. *Intermittent Linkwork—Click and Ratchet.*—A click acting upon a ratchet-wheel or rack, which it pushes or pulls through a certain arc at each forward stroke and leaves at rest at each backward stroke, is an example of intermittent linkwork. During the forward stroke the action of the click is governed by the principles of linkwork; during the backward stroke that action ceases. A catch or pull, turning on a fixed axis, prevents the ratchet-wheel or rack from reversing its motion.

#### Division 5. Trains of Mechanism.

78. *General Principles.*—A train of mechanism consists of a series of pieces each of which is follower to that which drives it and driver to that which follows it.

The comparative motion of the first driver and last follower is obtained by combining the proportions expressing by their terms the velocity ratios and by their signs the directional relations of the several elementary combinations of which the train consists.

79. *Trains of Wheelwork.*—Let  $A_1$ ,  $A_2$ ,  $A_3$ , &c.,  $A_{m-1}$ ,  $A_m$  denote a series of axes, and  $a_1$ ,  $a_2$ ,  $a_3$ , &c.,  $a_{m-1}$ ,  $a_m$  their angular velocities. Let the axis  $A_1$  carry a wheel of  $N_1$  teeth, driving a wheel of  $n_2$  teeth on the axis  $A_2$ , which carries also a wheel of  $N_2$  teeth, driving a wheel of  $n_3$  teeth on the axis  $A_3$ , and so on; the numbers of teeth in drivers being denoted by  $N$ 's, and in followers by  $n$ 's, and the axes to which the wheels are fixed being denoted by numbers. Then the resulting velocity ratio is denoted by

$$\frac{a_m}{a_1} = \frac{a_2}{a_1} \cdot \frac{a_3}{a_2} \cdot \text{&c.} \dots \frac{a_m}{a_{m-1}} = \frac{N_1 \cdot N_2 \cdot \text{&c.} \dots N_{m-1}}{n_2 \cdot n_3 \cdot \text{&c.} \dots n_m} \quad (41);$$

that is to say, the velocity ratio of the last and first axes is the ratio of the product of the numbers of teeth in the drivers to the product of the numbers of teeth in the followers.

Supposing all the wheels to be in outside gearing, then, as each elementary combination reverses the direction of rotation, and as the number of elementary combinations  $m-1$  is one less than the number of axes  $m$ , it is evident that if  $m$  is odd the direction of rotation is preserved, and if even reversed.

It is often a question of importance to determine the number of teeth in a train of wheels best suited for giving a determinate velocity ratio to two axes. It was shown by Young that, to do this with the least total number of teeth, the velocity ratio of each elementary combination should approximate as nearly as possible to 3.59. This would in many cases give too many axes; and, as a useful practical rule, it may be laid down that from 3 to 6 ought to be the limit of the velocity ratio of an elementary combination in wheelwork. The smallest number of teeth in a pinion for epicycloidal teeth ought to be twelve (see sect. 59),—but it is better, for smoothness of motion, not to go below fifteen; and for involute teeth the smallest number is about twenty-four.

Let  $\frac{B}{C}$  be the velocity ratio required, reduced to its least terms, and let  $B$  be greater than  $C$ . If  $\frac{B}{C}$  is not greater than 6, and  $C$  lies between the prescribed minimum number of teeth (which may be

called  $t$ ) and its double  $2t$ , then one pair of wheels will answer the purpose, and  $B$  and  $C$  will themselves be the numbers required. Should  $B$  and  $C$  be inconveniently large, they are, if possible, to be resolved into factors, and those factors (or if they are too small, multiples of them) used for the number of teeth. Should  $B$  or  $C$ , or both, be at once inconveniently large and prime, then, instead of the exact ratio  $\frac{B}{C}$ , some ratio approximating to that ratio, and capable of resolution into convenient factors, is to be found by the method of continued fractions.

Should  $\frac{B}{C}$  be greater than 6, the best number of elementary combinations  $m-1$  will lie between

$$\frac{\log B - \log C}{\log 6} \text{ and } \frac{\log B - \log C}{\log 3}.$$

Then, if possible,  $B$  and  $C$  themselves are to be resolved each into  $m-1$  factors (counting 1 as a factor), which factors, or multiples of them, shall be not less than  $t$  nor greater than  $6t$ ; or if  $B$  and  $C$  contain inconveniently-large prime factors, an approximate velocity ratio, found by the method of continued fractions, is to be substituted for  $\frac{B}{C}$  as before.

So far as the resultant velocity ratio is concerned, the order of the drivers  $N$  and of the followers  $n$  is immaterial; but to secure equable wear of the teeth, as explained in sect. 54, the wheels ought to be so arranged that, for each elementary combination, the greatest common divisor of  $N$  and  $n$  shall be either 1, or as small as possible.

80. *Double Hooke's Coupling.*—It has been shown in section 76 that the velocity ratio of a pair of shafts coupled by a universal joint fluctuates between the limits  $\cos \theta$  and  $\frac{1}{\cos \theta}$ . Hence one or both

of the shafts must have a vibratory and unsteady motion, injurious to the mechanism and framework. To obviate this evil a short intermediate shaft is introduced, making equal angles with the first and last shaft, coupled with each of them by a Hooke's joint, and having its own two forks in the same plane. Let  $a_1$ ,  $a_2$ ,  $a_3$  be the angular velocities of the first, intermediate, and last shaft in this train of two Hooke's couplings. Then, from the principles of sect.

76 it is evident that at each instant  $\frac{a_2}{a_1} = \frac{a_2}{a_3}$ , and consequently that  $a_3 = a_1$ ; so that the fluctuations of angular velocity ratio caused by the first coupling are exactly neutralized by the second, and the first and last shafts have equal angular velocities at each instant.

81. *Converging and Diverging Trains of Mechanism.*—Two or more trains of mechanism may converge into one,—as when the two pistons of a pair of steam-engines, each through its own connecting-rod, act upon one crank-shaft. One train of mechanism may diverge into two or more,—as when a single shaft, driven by a prime mover, carries several pulleys, each of which drives a different machine. The principles of comparative motion in such converging and diverging trains are the same as in simple trains.

#### Division 6. Aggregate Combinations.

82. *General Principles.*—Willis has designated as "aggregate combinations" those assemblages of pieces of mechanism in which the motion of one follower is the resultant of component motions impressed on it by more than one driver. Two classes of aggregate combinations may be distinguished which, though not different in their actual nature, differ in the data which they present to the designer, and in the method of solution to be followed in questions respecting them.

Class I. comprises those cases in which a piece  $A$  is not carried directly by the frame  $C$ , but by another piece  $B$ , relatively to which the motion of  $A$  is given,—the motion of the piece  $B$  relatively to the frame  $C$  being also given. Then the motion of  $A$  relatively to the frame  $C$  is the resultant of the motion of  $A$  relatively to  $B$  and of  $B$  relatively to  $C$ ; and that resultant is to be found by the principles already explained in division 3 of this chapter, sects. 34 to 41.

Class II. comprises those cases in which the motions of three points in one follower are determined by their connexions with two or with three different drivers, so that the motion of the follower, as a whole, is to be determined by the principles of §§ 71, 78, pp. 690, 692.

This classification is founded on the kinds of problems arising from the combinations. Willis adopts another classification, founded on the objects of the combinations, which objects he divides into two classes, viz., (1) to produce aggregate velocity, or a velocity which is the resultant of two or more components in the same path, and (2) to produce an aggregate path, that is, to make a given point in a rigid body move in an assigned path by communicating certain motions to other points in that body.

It is seldom that one of these effects is produced without at the same time producing the other; but the classification of Willis

depends upon which of those two effects, even supposing them to occur together, is the practical object of the mechanism.

83. *Reduplication of Cords—Differential Windlass—Blocks, Sheaves, and Tackle.*—The axis C (fig. 26) carries a larger barrel AE and a smaller barrel DB, rotating as one piece with the angular velocity  $\alpha_1$  in the direction AE. The pulley or sheave FG has a weight W hung to its centre. A cord has one end made fast to and wrapped round the barrel AE; it passes from A under the sheave FG, and has the other end wrapped round and made fast to the barrel BD. Required the relation between the velocity of translation  $v_2$  of W and the angular velocity  $\alpha_1$  of the differential barrel.

Fig. 26.

In this case  $v_2$  is an aggregate velocity, produced by the joint action of the two drivers AE and BD, transmitted by wrapping connectors to FG, and combined by that sheave so as to act on the follower W, whose motion is the same with that of the centre of FG.

The velocity of the point F is  $\alpha_1 \cdot AC$ , upward motion being considered positive. The velocity of the point G is  $-\alpha_1 \cdot CB$ , downward motion being negative. Hence (p. 690, §§ 71, 72) the instantaneous axis of the sheave FG is in the diameter FG, at the distance

$$\frac{FG}{2} \cdot \frac{AC - BC}{AC + BC}$$

from the centre towards G; the angular velocity of the sheave is

$$\alpha_2 = \alpha_1 \cdot \frac{AC + BC}{FG};$$

and, consequently, the velocity of its centre is

$$v_2 = \alpha_2 \cdot \frac{FG}{2} \cdot \frac{AC - BC}{AC + BC} = \frac{\alpha_1 (AC - BC)}{2} \quad (42),$$

or the mean between the velocities of the two vertical parts of the cord.

If the cord be fixed to the frame-work at the point B, instead of being wound on a barrel, the velocity of W is half that of AF.

A case containing several sheaves is called a *block*. A *fall-block* is attached to a fixed point; a *running-block* is movable to and from a fall-block, with which it is connected by two or more plies of a rope. The whole combination constitutes a *tackle* or *purchase*.

The two plies of a rope at opposite sides of a sheave in the fall-block have equal and opposite velocities. The two plies at opposite sides of a sheave in the running-block have velocities (as in the case of the sheave FG) differing equally in opposite directions from the velocity of the running-block.

One end of the rope is fastened either to the fall-block or the running-block. The other, or free end, is called the *fall*. Let  $v_1$  be the velocity of the fall,  $v_2$  that of the running-block; and let it be required to find their ratio; and let velocities towards the fall-block be positive, and from it negative.

CASE 1. If the fastened end of the rope be attached to the fall-block its velocity is 0, and this also is the velocity of the first ply. The rope passes under a sheave in the running-block, so that the velocity of the second ply is  $2v_2$ . It then passes over a sheave in the fall-block; the velocity of the third ply is  $-2v_2$ ; then under a sheave in the running-block; the velocity of the fourth ply is  $4v_2$ ; and so on,—the general law being this:—let  $n$  be an even number, then

$$\left. \begin{aligned} \text{the velocity of the } n^{\text{th}} \text{ ply} &= nv_2 \\ \text{the velocity of the } (n+1)^{\text{th}} \text{ ply} &= -nv_2 \\ &= -v_1, \text{ if the fall be the } (n+1)^{\text{th}} \text{ ply} \end{aligned} \right\} \quad (43).$$

CASE 2. If the fastened end of the rope be attached to the running-block, the velocity of the first ply is  $v_2$ ; of the second,  $-v_2$ ; of the third,  $3v_2$ ; of the fourth,  $-3v_2$ ; and, generally, if  $n$  be an odd number,

$$\left. \begin{aligned} \text{velocity of the } n^{\text{th}} \text{ ply} &= nv_2 \\ \text{the velocity of the } (n+1)^{\text{th}} \text{ ply} &= -nv_2 \\ &= -v_1, \text{ if the fall be the } (n+1)^{\text{th}} \text{ ply} \end{aligned} \right\} \quad (44).$$

Generally,—

$$\frac{v_1}{v_2} = -n \quad (45),$$

where  $n$  is the number of plies of rope by which the running-block hangs.

The sheaves in a block are usually made all of the same diameter, and turn on a fixed pin, and they have, consequently, different angular velocities. But by making the diameter of each sheave proportional to the velocity, relatively to the block, of the ply of rope which it is to carry, the angular velocities of the sheaves in one block may be rendered equal, so that the sheaves may be made all in one piece, and may have journals turning in fixed bearings. This is called *White's tackle*, from the inventor.

For details and technical terms see SHIPBUILDING.

84. *Differential Screw.*—On the same axis let there be two screws of the respective pitches  $p_1$  and  $p_2$ , made in one piece, and rotating with the angular velocity  $\alpha$ . Let this piece be called B. Let the first screw turn in a fixed nut C, and the second in a sliding nut A. The velocity of advance of B relatively to C is (according to sect. 41)  $\alpha p_1$ , and of A relatively to B (according to sect. 67)  $-\alpha p_2$ ; hence the velocity of A relatively to C is

$$\alpha(p_1 - p_2) \quad (46),$$

being the same with the velocity of advance of a screw of the pitch  $p_1 - p_2$ . This combination, called *Hunter's* or the *differential screw*, combines the strength of a large thread with the slowness of motion due to a small one.

85. *Epicyclic Trains.*—The term *epicyclic train* is used by Willis to denote a train of wheels carried by an arm, and having certain rotations relatively to that arm, which itself rotates. The arm may either be driven by the wheels or assist in driving them. The comparative motions of the wheels and of the arm, and the aggregate paths traced by points in the wheels, are determined by the principles of the composition of rotations, and of the description of rolling curves, explained in sects. 37 to 40.

86. *Link Motion.*—Let S (fig. 27) be the shaft of a steam-engine, O its axis,  $E_f$  the forward eccentric, suitably placed for moving the slide-valve when the shaft rotates forwards, F its centre,  $O_f$  its crank-arm,  $C_f$  its rod,  $E_b$  the backward eccentric, suitably placed for moving the slide-valve when the shaft rotates backwards, B its centre,  $O_b$  its crank-arm,  $C_b$  its rod. L is a long narrow box called the *link*, jointed at  $T_f$  and  $T_b$  to the eccentric rods; R is the valve-rod which works the slide-valve, jointed to P, a slider, which, by moving either L or R, or both, can be adjusted to any required position in the link. When P is at  $T_f$  the valve is said to be in *full forward gearing*, being acted upon by  $E_f$  alone. When P is at  $T_b$  the valve is said to be in *full backward gearing*, being acted upon by  $E_b$  alone. When P is placed in an intermediate position, the valve has an aggregate motion due to the joint action of  $E_f$  and  $E_b$ . The most exact mode of determining that motion is to make a skeleton drawing of the apparatus in various positions; but an approximation to the motion of the valve may be obtained by joining FB, and taking Q so that

Fig. 27.

then the valve will move nearly as if it were worked by one eccentric, having its centre at Q.

$$T_f P : T_b P :: FQ : BQ;$$

then the valve will move nearly as if it were worked by one eccentric, having its centre at Q.

87. *Parallel Motions (exact).*—A *parallel motion* is a combination of turning pieces in mechanism designed to guide the motion of a reciprocating piece either exactly or approximately in a straight line, so as to avoid the friction which arises from the use of straight guides for that purpose.

Fig. 28 represents an exact parallel motion, first proposed, it is believed, by Mr Scott Russell.

The arm CD turns on the axis C, and is jointed at D to the middle of the bar ADB, whose length is double of that of CD, and one of whose ends B is jointed to a slider, sliding in straight guides along the line OB. Draw BE perpendicular to CB, cutting CD produced in E, then E is the instantaneous axis of the bar ADB; and the direction of motion of A is at every instant perpendicular to EA, that is, along the straight line ACa. While the stroke of A is ACa, extending to equal distances on either side of C, and equal to twice the chord of the arc Dd, the stroke of B is only equal to twice the sagitta; and thus A is guided through a comparatively long stroke by the sliding of B through a comparatively short stroke, and by rotatory motions at the joints C, D, B. (For details, see STEAM-ENGINE.)

Fig. 28.

88. *Parallel Motion—Watt's Approximate* (see fig. 29).—Let CT, ct be a pair of levers connected by a link Tt, and oscillating about the axes Cc between the positions marked 1 and 3. Let the middle positions of the levers CT, ct be parallel to each other. It is required to find a point P in the link Tt such that its middle

position  $P_2$  and its extreme positions  $P_1, P_3$  shall be in the same straight line  $SS$ , perpendicular to  $CT_2, ct_2$ , and so to place the axes  $C, c$  on the lines  $CT_2, ct_2$  that the path of  $P$  between the positions  $P_1, P_2, P_3$  shall be as near as possible to a straight line.

Fig. 29.

The axes  $C, c$  are to be so placed that the middle  $M$  of the versed sine  $VT_2$ , and the middle  $m$  of the versed sine  $vt_2$ , of the respective arcs whose equal chords  $T_1T_3, t_1t_3$  represent the stroke, may each be in the line  $SS$ . Then  $T_1$  and  $T_3$  will be as far to one side of  $SS$  as  $T_2$  is to the other, and  $t_1$  and  $t_3$  will be as far to the latter side of  $SS$  as  $t_2$  is to the former; consequently, the two extreme positions of the links  $T_1t_1, T_3t_3$  are parallel to each other, and inclined to  $SS$  at the same angle in one direction that the middle position of the link  $T_2t_2$  is inclined to that line in the other direction, and the three intersections  $P_1, P_2, P_3$  are at the same point on the link.

The position of the point  $P$  on the link is found by the following proportional equation:—

$$\left. \begin{aligned} Tt : PT : Pt \\ :: TV : tv : TV : tv \\ :: CM + cm : cm : CM \end{aligned} \right\} \dots \dots \dots (47).$$

Suppose the axes  $C, c$  to be given, the line of stroke  $SS$ , and the length of stroke  $L = T_1T_3 = t_1t_3$ , and that it is required to find the dimensions of the levers and link. Let fall  $CM$  and  $cm$  perpendicular to  $SS$ ; then

$$\left. \begin{aligned} TV &= \frac{L^2}{8CM}; \quad tv = \frac{L^2}{8cm}; \\ CT &= CM + \frac{1}{2}TV; \quad ct = cm + \frac{1}{2}tv; \\ Tt &= \sqrt{\{Mm^2 + \frac{1}{4}(TV + tv)^2\}} \end{aligned} \right\} \dots \dots \dots (48).$$

If  $C$  and  $c$  are at the same side of  $SS$ , the smaller of the two perpendiculars is to be treated as negative in the formulæ, and the difference of the versed sines used instead of their sum; and the point  $P$  will lie in the prolongation of the link beyond  $Tt$  to the side of the longer lever. When the arcs of oscillation of the levers on either side of their middle positions do not exceed  $20^\circ$ , the intermediate portions of the path of  $P$  between  $P_1, P_2$ , and  $P_3$  are near enough to a straight line for practical purposes; and that point may be used to guide a sliding piece, such as the piston-rod of a steam-engine, for which purpose this parallel motion was originally invented by Watt.

## CHAPTER II. ON APPLIED DYNAMICS.

89. *Laws of Motion.*—The action of a machine in transmitting force and motion simultaneously, or performing work, is governed, in common with the phenomena of moving bodies in general, by two "laws of motion," for which see pp. 676 sq.

90. *Comparison of Deviating Force with Gravity.*—See pp. 698, 699, §§ 104–106.

91. *Deviating Forces Classified—Deflecting Force—Accelerating and Retarding Forces.*—See p. 701, §§ 114–119.

92. *Division of the Subject.*—On this classification of the deviating forces in machines is founded the following division of the subject of dynamics as applied to machines:—

Division 1.—Balanced forces in machines of uniform velocity.

Division 2.—Deflecting forces in such machines.

Division 3.—Working of machines of varying velocity.

Division 1. *Balanced Forces in Machines of Uniform Velocity.*

93. *Application of Force to Mechanism.*—Forces are applied in units of weight; and the unit most commonly employed in Britain is the *pound avoirdupois*. The action of a force applied to a body

is always in reality distributed over some definite space, either a volume of three dimensions or a surface of two. An example of a force distributed throughout a volume is the *weight* of the body itself, which acts on every particle, however small. The *pressure* exerted between two bodies at their surface of contact, or between the two parts of one body on either side of an ideal surface of separation, is an example of a force distributed over a surface. The mode of distribution of a force applied to a solid body requires to be considered when its stiffness and strength are treated of; but, in questions respecting the action of a force upon a rigid body considered as a whole, the *resultant* of the distributed force, determined according to the principles of statics, and considered as acting in a *single line* and applied at a *single point*, may, for the occasion, be substituted for the force as really distributed. Thus, the weight of each separate piece in a machine is treated as acting wholly at its *centre of gravity*, and each pressure applied to it as acting at a point called the *centre of pressure* of the surface to which the pressure is really applied.

94. *Forces applied to Mechanism Classified.*—If  $\theta$  be the obliquity of a force  $F$  applied to a piece of a machine,—that is, the angle made by the direction of the force with the direction of motion of its point of application,—then by the principles of Statics,  $F$  may be resolved into two rectangular components, viz.:—

$$\left. \begin{aligned} \text{Along the direction of motion, } P &= F \cos \theta \\ \text{Across the direction of motion, } Q &= F \sin \theta \end{aligned} \right\} \dots \dots (49).$$

If the component along the direction of motion acts *with* the motion, it is called an *effort*; if *against* the motion, a *resistance*. The component *across* the direction of motion is a *lateral pressure*; the unbalanced lateral pressure on any piece, or part of a piece, is *deflecting force*. A lateral pressure may increase resistance by causing friction; the friction so caused acts against the motion, and is a resistance, but the lateral pressure causing it is not a resistance. Resistances are distinguished into *useful* and *prejudicial*, according as they arise from the useful effect produced by the machine or from other causes.

95. *Work.*—*Work* consists in moving against resistance. The work is said to be *performed*, and the resistance *overcome*. Work is measured by the product of the resistance into the distance through which its point of application is moved. The *unit of work* commonly used in Britain is a resistance of one pound overcome through a distance of one foot, and is called a *foot-pound*.

Work is distinguished into *useful work* and *prejudicial or lost work*, according as it is performed in producing the useful effect of the machine, or in overcoming prejudicial resistance.

96. *Energy—Potential Energy.*—*Energy* means *capacity for performing work*. The *energy of an effort*, or *potential energy*, is measured by the product of the effort into the distance through which its point of application is *capable* of being moved. The unit of energy is the same with the unit of work.

When the point of application of an effort has been moved through a given distance, energy is said to have been *exerted* to an amount expressed by the product of the effort into the distance through which its point of application has been moved.

97. *Variable Effort and Resistance.*—If an effort has different magnitudes during different portions of the motion of its point of application through a given distance, let each different magnitude of the effort  $P$  be multiplied by the length  $\Delta s$  of the corresponding portion of the path of the point of application; the sum

$$\Sigma P \Delta s \dots \dots \dots (50)$$

is the whole energy exerted. If the effort varies by insensible gradations, the energy exerted is the integral or limit towards which that sum approaches continually as the divisions of the path are made smaller and more numerous, and is expressed by

$$\int P ds \dots \dots \dots (51).$$

Similar processes are applicable to the finding of the work performed in overcoming a varying resistance.

98. *Dynamometer or Indicator.*—A dynamometer or indicator is an instrument which measures and records the energy exerted by an effort. It usually consists essentially, first, of a piece of paper moving with a velocity proportional to that of the point of application of the effort, and having a straight line marked on it parallel to its direction of motion, called the zero line; and, secondly, of a spring acted upon and bent by the effort, and carrying a pencil whose perpendicular distance from the zero line, as regulated by the bending of the spring, is proportional to the effort. The pencil traces on the piece of paper a line such that its *ordinate* perpendicular to the zero line at a given point represents the effort  $P$  for the corresponding point in the path of the point of effort, and the *area between two ordinates* represents the energy exerted,  $\int P ds$ , for the corresponding portion of the path of the point of effort.

99. *Principle of the Equality of Energy and Work.*—From the first law of motion it follows that in a machine whose pieces move with uniform velocities the efforts and resistances must balance each

other. Now from the laws of statics (see above) it is known that, in order that a system of forces applied to a system of connected points may be in equilibrium, it is necessary that the sum formed by putting together the products of the forces by the respective distances through which their points of application are capable of moving simultaneously, each along the direction of the force applied to it, shall be zero,—products being considered positive or negative according as the direction of the forces and the possible motions of their points of application are the same or opposite.

In other words, the sum of the negative products is equal to the sum of the positive products. This principle, applied to a machine whose parts move with uniform velocities, is equivalent to saying that in any given interval of time the energy exerted is equal to the work performed.

The symbolical expression of this law is as follows:—let efforts be applied to one or any number of points of a machine; let any one of these efforts be represented by  $P$ , and the distance traversed by its point of application in a given interval of time by  $ds$ ; let resistances be overcome at one or any number of points of the same machine; let any one of these resistances be denoted by  $R$ , and the distance traversed by its point of application in the given interval of time by  $ds'$ ; then

$$\Sigma Pds = \Sigma Rds' \quad \dots \dots \dots (52).$$

The lengths  $ds$ ,  $ds'$  are proportional to the velocities of the points to whose paths they belong; and the proportions of those velocities to each other are deducible from the construction of the machine by the principles of pure mechanism explained in Chapter I.

100. *Efficiency*.—The efficiency of a machine is the ratio of the useful work to the total work,—that is, to the energy exerted,—and is represented by

$$\frac{\Sigma Ruds'}{\Sigma Rds} = \frac{\Sigma Ruds'}{\Sigma Ruds' + \Sigma R_p ds'} = \frac{\Sigma Ruds'}{\Sigma Pds} = \frac{U}{E} \quad \dots \dots (53),$$

$R_u$  being taken to represent useful and  $R_p$  prejudicial resistances.

The more nearly the efficiency of a machine approaches to unity the better is the machine.

101. *Power and Effect*.—The power of a machine is the energy exerted, and the effect the useful work performed, in some interval of time of definite length, such as a second, an hour, or a day.

The unit of power, called conventionally a *horse-power*, is 550 foot-pounds per second, or 33,000 foot-pounds per minute, or 1,980,000 foot-pounds per hour.

102. *Modulus of a Machine*.—In the investigation of the properties of a machine, the useful resistances to be overcome and the useful work to be performed are usually given. The prejudicial resistances are generally functions of the useful resistances of the weights of the pieces of the mechanism, and of their form and arrangement; and, having been determined, they serve for the computation of the lost work, which, being added to the useful work, gives the expenditure of energy required. The result of this investigation, expressed in the form of an equation between this energy and the useful work, is called by Moseley the *modulus* of the machine. The general form of the modulus may be expressed thus—

$$E = U + \phi(U, A) + \psi(A) \quad \dots \dots \dots (54),$$

where  $A$  denotes some quantity or set of quantities depending on the form, arrangement, weight, and other properties of the mechanism. Moseley, however, has pointed out that in most cases this equation takes the much more simple form of

$$E = (1 + A)U + B, \quad \dots \dots \dots (55),$$

where  $A$  and  $B$  are constants, depending on the form, arrangement, and weight of the mechanism. The efficiency corresponding to the last equation is

$$\frac{U}{E} = \frac{1}{1 + A + B/U} \quad \dots \dots \dots (56).$$

103. *Trains of Mechanism*.—In applying the preceding principles to a train of mechanism, it may either be treated as a whole, or it may be considered in sections consisting of single pieces, or of any convenient portion of the train,—each section being treated as a machine driven by the effort applied to it and energy exerted upon it through its line of connexion with the preceding section, performing useful work by driving the following section, and losing work by overcoming its own prejudicial resistances.

It is evident that the efficiency of the whole train is the product of the efficiencies of its sections.

104. *Rotating Pieces—Couples of Forces*.—It is often convenient to express the energy exerted upon and the work performed by a turning piece in a machine in terms of the *moment* of the couples of forces acting on it, and of the angular velocity. See p. 728, § 219.

The ordinary British unit of moment is a *foot-pound*; but it is to be remembered that this is a foot-pound of a different sort from the unit of energy and work.

If a force be applied to a turning piece in a line not passing through its axis, the axis will press against its bearings with an equal and parallel force, and the equal and opposite reaction of the bearings will constitute, together with the first-mentioned force, a couple whose arm is the perpendicular distance from the axis to the line of action of the first force.

A couple is said to be *right* or *left handed* with reference to the observer, according to the direction in which it tends to turn the body, and is a *driving* couple or a *resisting* couple according as its tendency is with or against that of the actual rotation.

Let  $dt$  be an interval of time,  $\alpha$  the angular velocity of the piece; then  $\alpha dt$  is the angle through which it turns in the interval  $dt$ , and  $ds = vdt = radt$  is the distance through which the point of application of the force moves. Let  $P$  represent an effort, so that  $Pr$  is a driving couple, then

$$Pds = Pvd t = Pr \alpha dt = M \alpha dt \quad \dots \dots \dots (57)$$

is the energy exerted by the couple  $M$  in the interval  $dt$ ; and a similar equation gives the work performed in overcoming a resisting couple. When several couples act on one piece, the resultant of their moments is to be multiplied by the common angular velocity of the whole piece.

105. *Reduction of Forces to a given Point, and of Couples to the Axis of a given Piece*.—In computations respecting machines it is often convenient to substitute for a force applied to a given point, or a couple applied to a given piece, the *equivalent* force or couple applied to some other point or piece; that is to say, the force or couple, which, if applied to the other point or piece, would exert equal energy or employ equal work. The principles of this reduction are that the ratio of the given to the equivalent force is the reciprocal of the ratio of the velocities of their points of application, and the ratio of the given to the equivalent couple is the reciprocal of the ratio of the angular velocities of the pieces to which they are applied.

These velocity ratios are known by the construction of the mechanism, and are independent of the absolute speed.

106. *Balanced Lateral Pressure of Guides and Bearings*.—The most important part of the lateral pressure on a piece of mechanism is the reaction of its guides, if it is a sliding piece, or of the bearings of its axis, if it is a turning piece; and the balanced portion of this reaction is equal and opposite to the resultant of all the other forces applied to the piece, its own weight included. There may be or may not be an unbalanced component in this pressure, due to the deviated motion. Its laws will be considered in the sequel.

107. *Friction—Unguents*.—The most important kind of resistance in machines is the *friction* or *rubbing resistance* of surfaces which slide over each other. The *direction* of the resistance of friction is opposite to that in which the sliding takes place. Its *magnitude* is the product of the *normal pressure* or force which presses the rubbing surfaces together in a direction perpendicular to themselves into a specific constant already mentioned in Part I., sect. 13, as the *coefficient of friction*, which depends on the nature and condition of the surfaces of the unguent, if any, with which they are covered. The *total pressure* exerted between the rubbing surfaces is the resultant of the normal pressure and of the friction, and its *obliquity*, or inclination to the common perpendicular of the surfaces, is the *angle of repose* formerly mentioned in sect. 13, whose tangent is the coefficient of friction. Thus, let  $N$  be the normal pressure,  $R$  the friction,  $T$  the total pressure,  $f$  the coefficient of friction, and  $\phi$  the angle of repose; then

$$\left. \begin{aligned} f &= \tan \phi \\ R &= fN = N \tan \phi = T \sin \phi \end{aligned} \right\} \quad \dots \dots \dots (58).$$

Experiments on friction have been made by Coulomb, Vince, Rennie, Wood, D. Rankine, and others. The most complete and elaborate experiments are those of Morin, published in his *Notions Fondamentales de Mécanique*, and republished in Britain in the works of Moseley and Gordon. The following is an exceedingly condensed abstract of the most important results, as regards machines, of these experiments:—

| Surfaces.  | $f$ .         |
|--|---------------|
| Wood on wood, dry.....                                   | 0.25 to 0.5   |
| Do., soaped.....   | 0.2           |
| Metals on oak, dry.....                                  | 0.5 to 0.6    |
| Do., wet.....  | 0.24 to 0.26  |
| Do., soaped.....   | 0.2           |
| Do., elm, dry.....                                       | 0.3 to 0.25   |
| Hemp on oak, dry.....                                    | 0.53          |
| Do., wet.....  | 0.33          |
| Leather on oak, wet or dry.....                          | 0.27 to 0.35  |
| Leather on metals, dry.....                              | 0.56          |
| Do., wet.....  | 0.36          |
| Do., greasy.....   | 0.23          |
| Do., oiled.....  | 0.15          |
| Metals on metals, dry.....                               | 0.15 to 0.2   |
| Do., wet.....  | 0.30          |
| Smooth surfaces with unguents, occasionally greased..... | 0.07 to 0.08  |
| Do., do., well greased.....                              | 0.05          |
| Do., do., do., best results ....                         | 0.03 to 0.036 |

It is to be understood that the above-stated law of friction is only true for dry surfaces when the pressure is not sufficient to indent or abrade the surfaces, and for greased surfaces when the pressure is not sufficient to force out the unguent from between the surfaces. If the proper limit be exceeded, the friction increases more rapidly than in the simple ratio of the normal pressure.

The limit of pressure for unguents diminishes as the speed increases. The following are some of its approximate values as inferred from experience in railway locomotive and carriage axles:—

|   |     |     |     |
|---|-----|-----|-----|
| Velocity of rubbing in feet per second.....                         | 1   | 2½  | 5   |
| Intensity of normal pressure per lb per square inch of surface..... | 392 | 224 | 140 |

In pivots, the intensity of the pressure is usually fixed at about one ton per square inch.

Unguents should be comparatively thick for heavy pressures, that they may resist being forced out, and comparatively thin for light pressures, that their viscosity may not add to the resistance.

Unguents are of three classes, viz:—

1. *Fatty*: consisting of animal or vegetable fixed oils, such as tallow, lard, lard-oil, seal-oil, whale-oil, olive-oil. *Drying* oils, which absorb oxygen and harden, are obviously unfit for unguents.

2. *Soapy*: composed of fatty oil, alkali, and water. The best grease of this class should not contain more than about 25 or 30 per cent. of water; bad kinds contain 40 or 50 per cent. The additional water diminishes the cost, but spoils the unguent.

3. *Bituminous*: composed of solid and liquid mineral compounds of hydrogen and carbon.

108. *Work of Friction—Moment of Friction.*—The work performed in a unit of time in overcoming the friction of a pair of surfaces is the product of the friction by the velocity of sliding of the surfaces over each other, if that is the same throughout the whole extent of the rubbing surfaces. If that velocity is different for different portions of the rubbing surfaces, the velocity of each portion is to be multiplied by the friction of that portion, and the results summed or integrated.

When the relative motion of the rubbing surfaces is one of rotation, the work of friction in a unit of time, for a portion of the rubbing surfaces at a given distance from the axis of rotation, may be found by multiplying together the friction of that portion, its distance from the axis, and the angular velocity. The product of the force of friction by the distance at which it acts from the axis of rotation is called the *moment of friction*. The total moment of friction of a pair of rotating rubbing surfaces is the sum or integral of the moments of friction of their several portions.

To express this symbolically, let  $du$  represent the area of a portion of a pair of rubbing surfaces at a distance  $r$  from the axis of their relative rotation;  $p$  the intensity of the normal pressure at  $du$  per unit of area; and  $f$  the coefficient of friction. Then the moment of friction of  $du$  is

$$fprdu;$$

the total moment of friction is

$$\int fpr \cdot du;$$

and the work performed in a unit of time in overcoming friction, when the angular velocity is  $\alpha$ , is

$$\alpha \int fpr \cdot du.$$

It is evident that the moment of friction, and the work lost by being performed in overcoming friction, are less in a rotating piece as the bearings are of smaller radius. But a limit is put to the diminution of the radii of journals and pivots by the conditions of durability and of proper lubrication stated in sect. 107, and also by conditions of strength and stiffness.

109. *Total Pressure between Journal and Bearing.*—A single piece rotating with an uniform velocity has four mutually balanced forces applied to it:—(1) the effort exerted on it by the piece which drives it; (2) the resistance of the piece which follows it, which may be considered for the purposes of the present question as useful resistance; (3) its weight; and (4) the reaction of its own cylindrical bearings. There are given the following data:—

The direction of the effort.

The direction of the useful resistance.

The weight of the piece and the direction in which it acts.

The magnitude of the useful resistance.

The radius of the bearing  $r$ .

The angle of repose  $\phi$ , corresponding to the friction of the journal on the bearing.

And there are required the following:—

The direction of the reaction of the bearing.

The magnitude of that reaction.

The magnitude of the effort.

Let the useful resistance and the weight of the piece be compounded by the principles of statics into one force, and let this be called the *given force*.

The directions of the effort and of the given force are either

parallel or meet in a point. If they are parallel, the direction of the reaction of the bearing is also parallel to them; if they meet in a point, the direction of the reaction traverses the same point.

Also, let AAA, fig. 30, be a section of the bearing, and C its axis; then the direction of the reaction, at the point where it intersects the circle AAA, must make the angle  $\phi$  with the radius of that circle; that is to say, it must be a line such as PT touching the smaller circle BB, whose radius is  $r \cdot \sin \phi$ . The side on which it touches that circle is determined by the fact that the obliquity of the reaction is such as to oppose the rotation.

Fig. 30.

Thus is determined the direction of the reaction of the bearing; and the magnitude of that reaction and of the effort are then found by the principles of the equilibrium of three forces already stated in Part I., sect. 7 (see also p. 702, § 124).

The work lost in overcoming the friction of the bearing is the same with that which would be performed in overcoming at the circumference of the small circle BB a resistance equal to the whole pressure between the journal and bearing.

In order to diminish that pressure to the smallest possible amount, the effort, and the resultant of the useful resistance, and the weight of the piece (called above the "given force") ought to be opposed to each other as directly as is practicable consistently with the purposes of the machine.

110. *Friction of Pivots and Collars.*—When a shaft is acted upon by a force tending to shift it lengthways, that force must be balanced by the reaction of a bearing against a *pivot* at the end of the shaft; or, if that be impossible, against one or more *collars*, or rings projecting from the body of the shaft. The bearing of the pivot is called a *step* or *footstep*. Pivots require great hardness, and are usually made of steel. The *flat pivot* is a cylinder of steel having a plane circular end as a rubbing surface. Let  $N$  be the total pressure sustained by a flat pivot of the radius  $r$ ; if that pressure be uniformly distributed, which is the case when the rubbing surfaces of the pivot and its step are both true planes, the intensity of the pressure is

$$p = \frac{N}{\pi r^2} \dots \dots \dots (60);$$

and, introducing this value into equation 59, the *moment of friction of the flat pivot* is found to be

$$\frac{2}{3} f N r \dots \dots \dots (61),$$

or two-thirds of that of a cylindrical journal of the same radius under the same normal pressure.

The friction of a *conical pivot* exceeds that of a flat pivot of the same radius, and under the same pressure, in the proportion of the side of the cone to the radius of its base.

The moment of friction of a *collar* is given by the formula—

$$\frac{2}{3} f N \frac{r^3 - r'^3}{r^2 - r'^2} \dots \dots \dots (62),$$

where  $r$  is the external and  $r'$  the internal radius.

In the *cup and ball* pivot the end of the shaft and the step present two recesses facing each other, into which are fitted two shallow cups of steel or hard bronze. Between the concave spherical surfaces of those cups is placed a steel ball, being either a complete sphere or a lens having convex surfaces of a somewhat less radius than the concave surfaces of the cups. The moment of friction of this pivot is at first almost inappreciable from the extreme smallness of the radius of the circles of contact of the ball and cups, but, as they wear, that radius and the moment of friction increase.

It appears that the rapidity with which a rubbing surface wears away is proportional to the friction and to the velocity jointly, or nearly so. Hence the pivots already mentioned wear unequally at different points, and tend to alter their figures. Schiele has invented a pivot which preserves its original figure by wearing equally at all points in a direction parallel to its axis. The following are the principles on which this equality of wear depends:—

The rapidity of wear of a surface measured in an *oblique* direction is to the rapidity of wear measured normally as the secant of the obliquity is to unity. Let OX (fig. 31) be the axis of a pivot, and let RPC be a portion of a curve such that at any point P the secant of the obliquity to the normal of the curve of a line parallel to the axis is inversely proportional to the ordinate PY, to which the velocity of P is proportional. The rotation of that curve round OX will generate the form of pivot required. Now let PT be a tangent to the

Fig. 31.

proportional to the ordinate PY, to which the velocity of P is proportional. The rotation of that curve round OX will generate the form of pivot required. Now let PT be a tangent to the

curve at P, cutting OX in T;  $PT = PY \times \secant \text{ obliquity}$ , and this is to be a constant quantity; hence the curve is that known as the *tractory* of the straight line OX, in which  $PT = OR = \text{constant}$ . This curve is described by having a fixed straight edge parallel to OX, along which slides a slider carrying a pin whose centre is T. On that pin turns an arm, carrying at a point P a tracing-point, pencil, or pen. Should the pen have a nib of two jaws, like those of an ordinary drawing-pen, the plane of the jaws must pass through PT. Then, while T is slid along the axis from O towards X, P will be drawn after it from R towards C along the tractory. This curve, being an asymptote to its axis, is capable of being indefinitely prolonged towards X; but in designing pivots it should stop before the angle PTY becomes less than the angle of repose of the rubbing surfaces, otherwise the pivot will be liable to stick in its bearing.

The moment of friction of "Schiele's anti-friction pivot," as it is called, is equal to that of a cylindrical journal of the radius  $OR = PT$  the constant tangent, under the same pressure.

111. *Friction of Teeth*.—Let N be the normal pressure exerted between a pair of teeth of a pair of wheels;  $s$  the total distance through which they slide upon each other;  $n$  the number of pairs of teeth which pass the plane of axis in a unit of time; then

$$nFNs \dots \dots \dots (63)$$

is the work lost in unity of time by the friction of the teeth. The sliding  $s$  is composed of two parts, which take place during the approach and recess respectively. Let those be denoted by  $s_1$  and  $s_2$ , so that  $s = s_1 + s_2$ . In sect. 55 the velocity of sliding at any instant has been given, viz.,  $u = c(\alpha_1 + \alpha_2)$ , where  $u$  is that velocity,  $c$  the distance TI at any instant from the point of contact of the teeth to the pitch-point, and  $\alpha_1, \alpha_2$  the respective angular velocities of the wheels.

Let  $v$  be the common velocity of the two pitch-circles,  $r_1, r_2$  their radii; then the above equation becomes

$$u = cv \left( \frac{1}{r_1} + \frac{1}{r_2} \right).$$

To apply this to involute teeth, let  $c_1$  be the length of the approach,  $c_2$  that of the recess,  $u_1$  the mean velocity of sliding during the approach,  $u_2$  that during the recess; then

$$u_1 = \frac{c_1 v}{2} \left( \frac{1}{r_1} + \frac{1}{r_2} \right); u_2 = \frac{c_2 v}{2} \left( \frac{1}{r_1} + \frac{1}{r_2} \right)$$

also, let  $\theta$  be the obliquity of the action; then the times occupied by the approach and recess are respectively

$$\frac{c_1}{v \cos \theta}, \quad \frac{c_2}{v \cos \theta};$$

giving, finally, for the length of sliding between each pair of teeth,

$$s = s_1 + s_2 = \frac{c_1^2 + c_2^2}{2 \cos \theta} \left( \frac{1}{r_1} + \frac{1}{r_2} \right) \dots \dots \dots (64),$$

which, substituted in equation 63, gives the work lost in a unit of time by the friction of involute teeth. This result, which is exact for involute teeth, is approximately true for teeth of any figure.

For inside gearing, if  $r_1$  be the less radius and  $r_2$  the greater,  $\frac{1}{r_1} - \frac{1}{r_2}$  is to be substituted for  $\frac{1}{r_1} + \frac{1}{r_2}$ .

112. *Friction of Cords and Belts*.—A flexible band, such as a cord, rope, belt, or strap, may be used either to exert an effort or a resistance upon a pulley round which it wraps. In either case the tangential force, whether effort or resistance, exerted between the band and the pulley is their mutual friction, caused by and proportional to the normal pressure between them.

Let  $T_1$  be the tension of the free part of the band at that side towards which it tends to draw the pulley, or from which the pulley tends to draw it;  $T_2$  the tension of the free part at the other side;  $T$  the tension of the band at any intermediate point of its arc of contact with the pulley;  $\theta$  the ratio of the length of that arc to the radius of the pulley;  $d\theta$  the ratio of an indefinitely small element of that arc to the radius;  $F = T_1 - T_2$  the total friction between the band and the pulley;  $dF$  the elementary portion of that friction due to the elementary arc  $d\theta$ ;  $f$  the coefficient of friction between the materials of the band and pulley.

Then, according to a well-known principle in statics, the normal pressure at the elementary arc  $d\theta$  is  $Td\theta$ ,  $T$  being the mean tension of the band at that elementary arc; consequently the friction on that arc is  $dF = fTd\theta$ . Now that friction is also the difference between the tensions of the band at the two ends of the elementary arc, or  $dT = dF = fTd\theta$ ; which equation, being integrated throughout the entire arc of contact, gives the following formulæ:—

$$\left. \begin{aligned} \text{hyp. log. } \frac{T_1}{T_2} &= f\theta \dots \dots \dots \\ \frac{T_1}{T_2} &= e^{f\theta} \dots \dots \dots \\ F &= T_1 - T_2 = T_1(1 - e^{-f\theta}) = T_2(e^{f\theta} - 1) \end{aligned} \right\} \dots \dots \dots (65).$$

When a belt connecting a pair of pulleys has the tensions of its two sides originally equal, the pulleys being at rest, and when the pulleys are next set in motion, so that one of them drives the other by means of the belt, it is found that the advancing side of the belt is exactly as much tightened as the returning side is slackened, so that the mean tension remains unchanged. Its value is given by this formula—

$$\frac{T_1 + T_2}{2} = \frac{e^{f\theta} + 1}{2(e^{f\theta} - 1)} \dots \dots \dots (66),$$

which is useful in determining the original tension required to enable a belt to transmit a given force between two pulleys.

The equations 65 and 66 are applicable to a kind of *brake* called a *friction-strap*, used to stop or moderate the velocity of machines by being tightened round a pulley. The strap is usually of iron, and the pulley of hard wood.

Let  $a$  denote the arc of contact expressed in *turns and fractions of a turn*; then

$$\theta = 6.2832a$$

$$e^{f\theta} = \text{number whose common logarithm is } 2.7288fa \left\} \dots \dots \dots (67).$$

113. *Stiffness of Ropes*.—Ropes offer a resistance to being bent, and, when bent, to being straightened again, which arises from the mutual friction of their fibres. It increases with the sectional area of the rope, and is inversely proportional to the radius of the curve into which it is bent.

The work lost in pulling a given length of rope over a pulley is found by multiplying the length of the rope in feet by its stiffness in pounds, that stiffness being the excess of the tension at the leading side of the rope above that at the following side, which is necessary to bend it into a curve fitting the pulley, and then to straighten it again.

The following empirical formulæ for the stiffness of hempen ropes have been deduced by Morin from the experiments of Coulomb:—

Let  $F$  be the stiffness in pounds avoirdupois;  $d$  the diameter of the rope in inches,  $n = 48d^2$  for white ropes and  $35d^2$  for tarred ropes;  $r$  the effective radius of the pulley in inches;  $T$  the tension in pounds. Then

$$\left. \begin{aligned} \text{For white ropes, } F &= \frac{n}{r} (0.0012 + 0.001026n + 0.0012T) \\ \text{For tarred ropes, } F &= \frac{n}{r} (0.006 + 0.001392n + 0.00168T) \end{aligned} \right\} \dots \dots \dots (68).$$

114. *Friction-Couplings*.—Friction is useful as a means of communicating motion where sudden changes either of force or velocity take place, because, being limited in amount, it may be so adjusted as to limit the forces which strain the pieces of the mechanism within the bounds of safety. Amongst contrivances for effecting this object are *friction-cones*. A rotating shaft carries upon a cylindrical portion of its figure a wheel or pulley turning loosely on it, and consequently capable of remaining at rest when the shaft is in motion. This pulley has fixed to one side, and concentric with it, a short frustum of a hollow cone. At a small distance from the pulley the shaft carries a short frustum of a solid cone accurately turned to fit the hollow cone. This frustum is made always to turn along with the shaft by being fitted on a square portion of it, or by means of a rib and groove, or otherwise, but is capable of a slight longitudinal motion, so as to be pressed into, or withdrawn from, the hollow cone by means of a lever. When the cones are pressed together or engaged, their friction causes the pulley to rotate along with the shaft; when they are disengaged, the pulley is free to stand still. The angle made by the sides of the cones with the axis should not be less than the angle of repose. In the *friction-clutch*, a pulley loose on a shaft has a hoop or gland made to embrace it more or less tightly by means of a screw; this hoop has short projecting arms or ears. A fork or *clutch* rotates along with the shaft, and is capable of being moved longitudinally by a handle. When the clutch is moved towards the hoop, its arms catch those of the hoop, and cause the hoop to rotate and to communicate its rotation to the pulley by friction. There are many other contrivances of the same class, but the two just mentioned may serve for examples.

115. *Heat of Friction—Unguents*.—The work lost in friction is employed in producing heat. This fact is very obvious, and has been known from a remote period; but the exact determination of the proportion of the work lost to the heat produced, and the experimental proof that that proportion is the same under all circumstances, and with all materials, solid, liquid, and gaseous, are comparatively recent achievements of Joule. The quantity of work which produces a British unit of heat (or so much heat as elevates the temperature of one pound of pure water, at or near ordinary atmospheric temperatures, by one degree of Fahrenheit) is 772 foot-pounds. This constant, now designated as "Joule's equivalent," is the principal experimental datum of the science of thermodynamics.

The heat produced by friction, when moderate in amount, is useful in softening and liquefying thick unguents; but when excessive it

is prejudicial, by decomposing the unguents, and sometimes even by softening the metal of the bearings, and raising their temperature so high as to set fire to neighbouring combustible matters.

Excessive heating is prevented by a constant and copious supply of a good unguent. The elevation of temperature produced by the friction of a journal is sometimes used as an experimental test of the quality of unguents. When the velocity of rubbing is about 4 or 5 feet per second, the elevation of temperature has been found by some recent experiments to be, with good fatty and soapy unguents, 40° to 50° Fahr.; with good mineral unguents, about 30°.

116. *Rolling Resistance*.—By the rolling of two surfaces over each other without sliding a resistance is caused which is called sometimes "rolling friction," but more correctly *rolling resistance*. It is of the nature of a *couple*, resisting rotation. Its *moment* is found by multiplying the normal pressure between the rolling surfaces by an *arm*, whose length depends on the nature of the rolling surfaces, and the work lost in a unit of time in overcoming it is the product of its moment by the *angular velocity* of the rolling surfaces relatively to each other. The following are approximate values of the arm in decimals of a foot:—

|                              |                   |
|------------------------------|-------------------|
| Oak upon oak .....           | 0.006 (Coulomb).  |
| Lignum vitae on oak .....    | 0.004             |
| Cast iron on cast iron ..... | 0.002 (Tredgold). |

117. *Reciprocating Forces—Stored and Restored Energy*.—When a force acts on a machine alternately as an effort and as a resistance, it may be called a *reciprocating force*. Of this kind is the weight of any piece in the mechanism whose centre of gravity alternately rises and falls; for during the rise of the centre of gravity that weight acts as a resistance, and energy is employed in lifting it to an amount expressed by the product of the weight into the vertical height of its rise; and during the fall of the centre of gravity the weight acts as an effort, and exerts in assisting to perform the work of the machine an amount of energy exactly equal to that which had previously been employed in lifting it. Thus that amount of energy is not lost, but has its operation deferred; and it is said to be *stored* when the weight is lifted, and *restored* when it falls.

In a machine of which each piece is to move with a uniform velocity, if the effort and the resistance be constant, the weight of each piece must be balanced on its axis, so that it may produce lateral pressure only, and not act as a reciprocating force. But if the effort and the resistance be alternately in excess, the uniformity of speed may still be preserved by so adjusting some moving weight in the mechanism that when the effort is in excess it may be lifted, and so balance and employ the excess of effort, and that when the resistance is in excess it may fall, and so balance and overcome the excess of resistance,—thus *storing* the periodical excess of energy, and *restoring* that energy to perform the periodical excess of work.

Other forces besides gravity may be used as reciprocating forces for storing and restoring energy,—for example, the elasticity of a spring or of a mass of air.

In most of the delusive machines commonly called "perpetual motions," of which so many are patented in each year, and which are expected by their inventors to perform work without receiving energy, the fundamental fallacy consists in an expectation that some reciprocating force shall restore more energy than it has been the means of storing.

#### Division 2. Deflecting Forces.

118. *Deflecting Force for Translation in a Curved Path*.—In machinery, deflecting force is supplied by the tenacity of some piece, such as a crank, which guides the deflected body in its curved path, and is *unbalanced*, being employed in producing deflexion, and not in balancing another force.

119. *Centrifugal Force*.—See p. 682, § 35, and p. 701, § 119.

120. *Rectangular Resolution of Centrifugal Force*.—See p. 701, §§ 117 and 119.

121. *Centrifugal Force of a Rotating Body*.—The centrifugal force exerted by a rotating body on its axis of rotation is the same in magnitude as if the mass of the body were concentrated at its centre of gravity, and acts in a plane passing through the axis of rotation and the centre of gravity of the body.

The particles of a rotating body exert centrifugal forces on each other, which strain the body, and tend to tear it asunder; but these forces balance each other, and do not affect the resultant centrifugal force exerted on the axis of rotation.<sup>1</sup>

If the axis of rotation traverses the centre of gravity of the body, the centrifugal force exerted on that axis is nothing.

Hence, unless there be some reason to the contrary, each piece of a machine should be balanced on its axis of rotation; otherwise the centrifugal force will cause strains, vibration, and increased friction, and a tendency of the shafts to jump out of their bearings.

122. *Centrifugal Couples of a Rotating Body*.—Besides the tendency (if any) of the combined centrifugal forces of the particles of

<sup>1</sup> This is a particular case of a more general principle, that the motion of the centre of gravity of a body is not affected by the mutual actions of its parts, for the proof of which see p. 718, § 179.

a rotating body to shift the axis of rotation, they may also tend to turn it out of its original direction. The latter tendency is called a *centrifugal couple*, and vanishes for rotation about a principal axis (see p. 782, § 237).

It is essential to the steady motion of every rapidly rotating piece in a machine that its axis of rotation should not merely traverse its centre of gravity, but should be a permanent axis; for otherwise the centrifugal couples will increase friction, produce oscillation of the shaft, and tend to make it leave its bearings.

The principles of this and the preceding section are those which regulate the adjustment of the weight and position of the *counterpoises* which are placed between the spokes of the driving-wheels of locomotive engines.

123. *Revolving Pendulum—Governors*.—In fig. 32 AO represents an upright axis or spindle; B a weight called a *bob*, suspended by rod OB from a horizontal axis at O, carried by the vertical axis. When the spindle is at rest the bob hangs close to it; when the spindle rotates, the bob, being made to revolve round it, diverges until the resultant of the centrifugal force and the weight of the bob is a force acting at O in the direction OB, and then it revolves steadily in a circle. This combination is called a *revolving, centrifugal, or conical pendulum*. Revolving pendulums are usually constructed with *pairs* of rods and bobs, as OB, Ob, hung at opposite sides of the spindle, that the centrifugal forces exerted at the point O may balance each other.

Fig. 32.

In finding the position in which the bob will revolve with a given angular velocity  $\alpha$ , for most practical cases connected with machinery the mass of the rod may be considered as insensible compared with that of the bob. Let the bob be a sphere, and from the centre of that sphere draw BH=y perpendicular to OA. Let OH=z; let W be the weight of the bob, F its centrifugal force. Then the condition of its steady revolution is  $W : F :: z : y$ ; that is to say,  $\frac{y}{z} = \frac{F}{W} = \frac{y\alpha^2}{g}$ ; consequently

$$z = \frac{g}{\alpha^2} \quad \dots \quad (69).$$

Or, if  $n = \frac{\alpha}{2\pi} = \frac{1}{6.2832}$  be the number of turns or fractions of a turn in a second,

$$z = \frac{g}{4\pi^2 n^2} = \frac{0.8165 \text{ foot}}{n^2} = \frac{9.79771 \text{ inches}}{n^2} \quad \dots \quad (70);$$

z is called the *altitude of the pendulum*.

If the rod of a revolving pendulum be jointed, as in fig. 33, not to a point in the vertical axis, but to the end of a projecting arm C, the position in which the bob will revolve will be the same as if the rod were jointed to the point O, where its prolongation cuts the vertical axis.

Fig. 33.

A revolving pendulum is an essential part of most of the contrivances called *governors*, for regulating the speed of prime movers.

The earlier kinds of governors act on the prime mover by the variations of their altitude. Thus in Watt's steam-engine governor the rods, through a combination of levers and linkwork C, c, D, d (fig. 32), act on a lever EF, which acts upon the throttle-valve for the admission of steam so as to enlarge or contract its opening when the speed becomes too small or too great.

In a more recent kind of governors invented by the Messrs Siemens, which may be called *differential governors*, the regulation of the prime mover is effected by means of the difference between the velocity of a wheel driven by it and that of a wheel regulated by a revolving pendulum. Fig. 34 illustrates this class of governors. A is a vertical dead-centre or fixed shaft, about which the after-mentioned pieces turn; C is a pulley driven by the prime mover, and fixed to a bevel-wheel, which is seen below it; E is a bevel-wheel similar to the first, and having the same apex. To this wheel are hung the bobs B, of which there are

Fig. 34.

To this wheel are hung the bobs B, of which there are

usually four, although two only are shown. Those bobs form sectors of a ring, and are surrounded by a cylindrical casing F. When the bobs revolve with their proper velocity, they are adjusted so as nearly to touch this casing; should they exceed that velocity, they fly outwards and touch the casing, and are retarded by the friction. For practical purposes their velocity of rotation about the vertical axis may be considered constant. G, G are horizontal arms projecting from a socket which is capable of rotation about A, and carrying vertical bevel wheels which rest on E and support C, and transmit motion from C to E. There are usually four of the arms G, G with their wheels, though two only are shown. H is one of those arms which projects, and has a rod attached to its extremity to act on the throttle-valve of a steam-engine, the sluice of a water-wheel, or the regulator of the prime mover, of whatever sort it may be.

When C rotates with an angular velocity equal and contrary to that of E with its revolving pendulums, the arms G, G remain at rest; but should C deviate from that velocity, those arms rotate in one direction or the other, as the case may be, with an angular velocity equal to one half of the difference between the angular velocity of C and that of E, and continue in motion until the regulator is adjusted so that the prime mover shall impart to C an angular velocity exactly equal to that of the revolving pendulums.

There are various modifications of the differential governor, but they all act on the same principle.

### Division 3. Working of Machines of Varying Velocity.

124. *General Principles.*—In order that the velocity of every piece of a machine may be uniform, it is necessary that the forces acting on each piece should be always exactly balanced. Also, in order that the forces acting on each piece of a machine may be always exactly balanced, it is necessary that the velocity of that piece should be uniform.

An excess of the effort exerted on any piece, above that which is necessary to balance the resistance, is accompanied with acceleration; a deficiency of the effort, with retardation.

When a machine is being started from a state of rest, and brought by degrees up to its proper speed, the effort must be in excess; when it is being retarded for the purpose of stopping it, the resistance must be in excess.

An excess of effort above resistance involves an excess of energy exerted above work performed; that excess of energy is employed in producing acceleration.

An excess of resistance above effort involves an excess of work performed above energy expended; that excess of work is performed by means of the retardation of the machinery.

When a machine undergoes alternate acceleration and retardation, so that at certain instants of time, occurring at the end of intervals called *periods* or *cycles*, it returns to its original speed, then in each of those periods or cycles the alternate excesses of energy and of work neutralize each other; and at the end of each cycle the principle of the equality of energy and work stated in sect. 96, with all its consequences, is verified exactly as in the case of machines of uniform speed.

At intermediate instants, however, other principles have also to be taken into account, which are deduced from the second law of motion, sect. 89, as applied by the aid of the principles of sect. 90, to *direct deviation*, or acceleration and retardation.

125. *Energy of Acceleration and Work of Retardation for a Shifting Body.*—Let  $w$  be the weight of a body which has a motion of translation in any path, and in the course of the interval of time  $\Delta t$  let its velocity be increased at a uniform rate of acceleration from  $v_1$  to  $v_2$ . The rate of acceleration will be

$$\frac{dv}{dt} = \text{constant} = \frac{v_2 - v_1}{\Delta t};$$

and (p. 698, § 104) to produce this acceleration a uniform effort will be required, expressed by

$$P = \frac{w \cdot (v_2 - v_1)}{g \Delta t} \quad (71).$$

(The product  $\frac{wv}{g}$  of the mass of a body by its velocity is called its *momentum*; so that the effort required is found by dividing the increase of momentum by the time in which it is produced.)

To find the *energy* which has to be exerted to produce the acceleration from  $v_1$  to  $v_2$ , it is to be observed that the *distance* through which the effort  $P$  acts during the acceleration is

$$\Delta s = \frac{v_2 + v_1}{2} \Delta t;$$

consequently, the *energy of acceleration* is

$$P \Delta s = \frac{w(v_2 - v_1)(v_2 + v_1)}{2g} = \frac{w(v_2^2 - v_1^2)}{2g} \quad (72),$$

being proportional to the increase in the square of the velocity, and independent of the time.

In order to produce a *retardation* from the greater velocity  $v_2$  to the less velocity  $v_1$ , it is necessary to apply to the body a *resistance*, connected with the retardation and the time by an equation identical in every respect with equation 71, except by the substitution of a resistance for an effort; and in overcoming that resistance the body *performs work* to an amount determined by equation 72, putting  $R$ ds for  $P$ as.

126. *Energy Stored and Restored by Deviations of Velocity.*—Thus a body alternately accelerated and retarded, so as to be brought back to its original speed, performs work during its retardation exactly equal in amount to the energy exerted upon it during its acceleration; so that that energy may be considered as *stored* during the acceleration, and *restored* during the retardation, in a manner analogous to the operation of a reciprocating force (sect. 117).

Let there be given the mean velocity  $V = \frac{1}{2}(v_2 + v_1)$  of a body whose weight is  $w$ , and let it be required to determine the fluctuation of velocity  $v_2 - v_1$ , and the extreme velocities  $v_1, v_2$ , which that body must have, in order alternately to store and restore an amount of energy  $E$ . By equation 72 we have

$$E = \frac{w(v_2^2 - v_1^2)}{2g}$$

which, being divided by  $V = \frac{1}{2}(v_2 + v_1)$ , gives

$$\frac{E}{V} = \frac{w(v_2 - v_1)}{g};$$

and consequently

$$v_2 - v_1 = \frac{gE}{Vw} \quad (73).$$

The ratio of this fluctuation to the mean velocity, sometimes called the *unsteadiness* of the motion of the body, is

$$\frac{v_2 - v_1}{V} = \frac{gE}{V^2w} \quad (74).$$

127. *Actual Energy of a Shifting Body.*—The energy which must be exerted on a body of the weight  $w$ , to accelerate it from a state of rest up to a given velocity of translation  $v$ , and the equal amount of work which that body is capable of performing by overcoming resistance while being retarded from the same velocity of translation  $v$  to a state of rest, is

$$\frac{wv^2}{2g} \quad (75).$$

This is called the *actual energy* of the motion of the body, and is half the quantity which in some treatises is called *vis viva*.

The energy stored or restored, as the case may be, by the deviations of velocity of a body or a system of bodies, is the amount by which the actual energy is increased or diminished.

128. *Principle of the Conservation of Energy in Machines.*—The following principle, expressing the general law of the action of machines with a velocity uniform or varying, includes the law of the equality of energy and work stated in sect. 99 for machines of uniform speed.

In any given interval during the working of a machine, the energy exerted added to the energy restored is equal to the energy stored added to the work performed.

129. *Actual Energy of Circular Translation.—Moment of Inertia.*—Let a body of the weight  $w$  undergo translation in a circular path of the radius  $p$ , with the angular velocity of deflexion  $\alpha$ , so that the common linear velocity of all its particles is  $v = \alpha p$ . Then the actual energy of that body is

$$\frac{wv^2}{2g} = \frac{w\alpha^2 p^2}{2g} \quad (76).$$

By comparing this with the expression for the centrifugal force ( $w\alpha^2 p/g$ ), it appears that the actual energy of a revolving body is equal to the potential energy  $Fp/2$  due to the action of the deflecting force along one-half of the radius of curvature of the path of the body.

The product  $w\alpha^2 p/g$ , by which the half-square of the angular velocity is multiplied, is called the *moment of inertia* of the revolving body.

130. *Actual Energy and Moment of Inertia of Rotation.—Radius of Gyration.*—See p. 732, §§ 234–237.

131. *Examples of Radii of Gyration.*—See p. 733, § 238.

132. *Fly-wheels.*—A fly-wheel is a rotating piece in a machine, generally shaped like a wheel (that is to say, consisting of a rim with spokes), and suited to store and restore energy by the periodical variations in its angular velocity.

The principles according to which variations of angular velocity store and restore energy are the same with those of sect. 126, only substituting *moment of inertia* for *mass*, and *angular* for *linear* velocity.

Let  $W$  be the weight of a fly-wheel,  $R$  its radius of gyration,  $\alpha_2$  its maximum,  $\alpha_1$  its minimum, and  $A = \frac{1}{2}(\alpha_2 + \alpha_1)$  its mean angular velocity. Let

$$\frac{1}{S} = \frac{\alpha_2 - \alpha_1}{A}$$

denote the *unsteadiness* of the motion of the fly-wheel; the denominator  $S$  of this fraction is called the *steadiness*. Let  $e$  denote the quantity by which the energy exerted in each cycle of the working of the machine alternately exceeds and falls short of the work performed, and which has consequently to be alternately stored by acceleration and restored by retardation of the fly-wheel. The value of this *periodical excess* is—

$$e = \frac{R^2 W (a_2^2 - a_1^2)}{2g} \quad (77),$$

from which, dividing both sides by  $A^2$ , we obtain the following equations:—

$$\left. \begin{aligned} \frac{e}{A^2} &= \frac{R^2 W}{gS} \\ \frac{R^2 W A^2}{2g} &= \frac{Se}{2} \end{aligned} \right\} \quad (78).$$

The latter of these equations may be thus expressed in words:—*The actual energy due to the rotation of the fly, with its mean angular velocity, is equal to one-half of the periodical excess of energy multiplied by the steadiness.*

In ordinary machinery  $S$  = about 32; in machinery for fine purposes  $S$  = from 50 to 60.

The periodical excess  $e$  may arise either from variations in the effort exerted by the prime mover, or from variations in the resistance of the work, or from both these causes combined. When but one fly-wheel is used, it should be placed in as direct connexion as possible with that part of the mechanism where the greatest amount of the periodical excess originates; but when it originates at two or more points, it is best to have a fly-wheel in connexion with each of those points. For example, in a machine-work, the steam-engine, which is the prime mover of the various tools, has a fly-wheel on the crank-shaft to store and restore the periodical excess of energy arising from the variations in the effort exerted by the connecting-rod upon the crank; and each of the slotting machines, punching machines, rivetting machines, and other tools has a fly-wheel of its own to store and restore energy, so as to enable the very different resistances opposed to those tools at different times to be overcome without too great unsteadiness of motion.

According to the computation of General Morin, the periodical excess  $e$  in steam-engines with single cranks is from  $\frac{1}{10}$ th to nearly  $\frac{1}{4}$ th of the energy exerted during one revolution of the crank. For a pair of steam-engines driving one shaft, with a pair of cranks at right angles to each other, the value of  $e$  is one-fourth of its value for a single cranked engine of the same kind, and of the same power with the two combined.

The ordinary radius of gyration of a steam-engine fly-wheel is from three to five times the length of the crank-arm. (For further particulars on this subject, see STEAM-ENGINE.)

For tools performing useful work at intervals, and having only their own friction to overcome during the intermediate intervals,  $e$  should be assumed equal to the whole work performed at each separate operation.

**133. Brakes.**—A brake is an apparatus for stopping and diminishing the velocity of a machine by friction, such as the friction-strap already referred to in sect. 112. To find the distance  $s$  through which a brake, exerting the friction  $F$ , must rub in order to stop a machine having the total actual energy  $E$  at the moment when the brake begins to act, reduce, by the principles of sect. 105, the various efforts and other resistances of the machine which act at the same time with the friction of the brake to the rubbing surface of the brake, and let  $R$  be their resultant,—*positive* if resistance, *negative* if effort preponderates. Then

$$s = \frac{E}{F + R} \quad (79).$$

**134. Energy distributed between two Bodies—Projection and Propulsion.**—Hitherto the effort by which a machine is moved has been treated as a force exerted between a movable body and a fixed body, so that the whole energy exerted by it is employed upon the movable body, and none upon the fixed body. This conception is sensibly realized in practice when one of the two bodies between which the effort acts is either so heavy as compared with the other, or has so great a resistance opposed to its motion, that it may, without sensible error, be treated as fixed. But there are cases in which the motions of both bodies are appreciable, and must be taken into account,—such as the projection of projectiles, where the velocity of the *recoil* or backward motion of the gun bears an appreciable proportion to the forward motion of the projectile; and such as the propulsion of vessels, where the velocity of the water thrown backward by the paddle, screw, or other propeller bears a very considerable proportion to the velocity of the water moved forwards and sideways by the ship. In cases of this kind the energy exerted by the effort is *distributed* between the two bodies between which the effort is exerted in shares proportional to the velocities of the two bodies during the action of the

effort; and those velocities are to each other directly as the portions of the effort unbalanced by resistance on the respective bodies, and inversely as the weights of the bodies.

To express this symbolically, let  $W_1, W_2$  be the weights of the bodies;  $P$  the effort exerted between them;  $S$  the distance through which it acts;  $R_1, R_2$  the resistances opposed to the effort overcome by  $W_1, W_2$  respectively;  $E_1, E_2$  the shares of the whole energy  $E$  exerted upon  $W_1, W_2$  respectively. Then

$$\therefore \frac{W_2(P - R_1) + W_1(P - R_2)}{W_1 W_2} : \frac{P - R_1}{W_1} : \frac{P - R_2}{W_2} \left\{ \quad (80). \right.$$

If  $R_1 = R_2$ , which is the case when the resistance, as well as the effort, arises from the mutual actions of the two bodies, the above becomes,

$$\therefore \frac{E}{W_1 + W_2} : \frac{E_1}{W_1} : \frac{E_2}{W_2} \left\{ \quad (81); \right.$$

that is to say, the energy is exerted on the bodies in shares inversely proportional to their weights; and they receive accelerations inversely proportional to their weights, according to the principle of dynamics, already quoted in a note to sect. 121, that the mutual actions of a system of bodies do not affect the motion of their common centre of gravity.

For example, if the weight of a gun be 160 times that of its ball,  $\frac{160}{161}$  of the energy exerted by the powder in exploding will be employed in propelling the ball, and  $\frac{1}{161}$  in producing the recoil of the gun, provided the gun up to the instant of the ball's quitting the muzzle meets with no resistance to its recoil except the friction of the ball.

**135. Centre of Percussion.**—It is obviously desirable that the deviations or changes of motion of oscillating pieces in machinery should, as far as possible, be effected by forces applied at their centres of percussion.

If the deviation be a *translation*,—that is, an equal change of motion of all the particles of the body,—the centre of percussion is obviously the centre of gravity itself; and, according to the second law of motion, if  $dv$  be the deviation of velocity to be produced in the interval  $dt$ , and  $W$  the weight of the body, then

$$P = \frac{W}{g} \cdot \frac{dv}{dt} \quad (82)$$

is the unbalanced effort required.

If the deviation be a rotation about an axis traversing the centre of gravity, there is no centre of percussion; for such a deviation can only be produced by a *couple* of forces, and not by any single force. Let  $da$  be the deviation of angular velocity to be produced in the interval  $dt$ , and  $I$  the moment of the inertia of the body; then  $\frac{1}{2}I d(a^2) = I da$  is the variation of the body's actual energy. Let  $M$  be the moment of the unbalanced couple required to produce the deviation; then, by equation 57, sect. 104, the energy exerted by this couple in the interval  $dt$  is  $M da$ , which, being equated to the variation of energy, gives

$$M = I \frac{da}{dt} = \frac{R^2 W}{g} \cdot \frac{da}{dt} \quad (83).$$

Now (fig. 35), let the required deviation be a rotation of the body  $BB$  about an axis  $O$ , not traversing the centre of gravity  $G$ ,  $da$  being, as before, the deviation of angular velocity to be produced in the interval  $dt$ . A rotation with the angular velocity  $a$  about an axis  $O$  may be considered as compounded of a rotation with the same angular velocity about an axis drawn through  $G$  parallel to  $O$  and a translation with the velocity  $a$ .  $OG, OG'$  being the perpendicular distance between the two axes. Hence the required deviation may be regarded as compounded of a deviation of translation  $dv = OG \cdot da$ , to produce which there would be required, according to equation 82, a force applied at  $G$  perpendicular to the plane  $OG$ —

$$P = \frac{W}{g} \cdot OG \cdot \frac{da}{dt} \quad (84),$$

and a deviation  $da$  of rotation about an axis drawn through  $G$  parallel to  $O$ , to produce which there would be required a couple of the moment  $M$  given by equation 83. According to the principles of statics, the resultant of the force  $P$ , applied at  $G$  perpendicular to the plane  $OG$ , and the couple  $M$  is a force equal and parallel to  $P$ , but applied at a distance  $GC$  from  $G$ , in the prolongation of the perpendicular  $OG$ , whose value is

$$GC = \frac{M}{P} = \frac{R^2}{P} \quad (85).$$

Thus is determined the position of the centre of percussion  $C$ , corresponding to the axis of rotation  $O$ . It is obvious from this equation that, for an axis of rotation parallel to  $O$  traversing  $C$ , the

Fig. 35.

centre of percussion is at the point where the perpendicular OG meets O.

136. *Impact.*—Impact or collision is a pressure of short duration exerted between two bodies. For the detailed investigation of its laws the reader is referred to MECHANICS, p. 719, § 180 sq.

The effects of impact are sometimes an alteration of the distribution of actual energy between the two bodies, and always a loss of a portion of that energy, depending on the imperfection of the elasticity of the bodies, in permanently altering their figures, and producing heat. The determination of the distribution of the actual energy after collision and of the loss of energy is effected by means of the following principles:—

I. The motion of the common centre of gravity of the two bodies is unchanged by the collision.

II. The loss of energy consists of a certain proportion of that part of the actual energy of the bodies which is due to their motion relatively to their common centre of gravity.

Unless there is some special reason for using impact in machines, it ought to be avoided, on account not only of the waste of energy which it causes, but from the damage which it occasions to the frame and mechanism.

### CHAPTER III. PURPOSES AND EFFECTS OF MACHINES.

137. *Observing Machines and Working Machines.*—The present chapter must necessarily be limited to some very general observations on the principal classes into which machines may be divided, with reference to their purposes and effects, leaving details of particular examples for treatment under the respective special headings.

Machines may be divided, in the first instance, into two great divisions, viz.:—

I. *Observing Machines*, in which either the modification of motion alone, or the balancing of forces alone, is the object in view,—the performance of work being either null or incidental, and being limited to that which arises from the resistance of the machine.

II. *Working machines*, in which the performance of work is the main object.

138. *Classification of Observing Machines.*—Observing machines might very properly have been classed as *instruments*, being designed to aid the human senses and memory in obtaining and recording information. They may be divided, in the first instance, into four classes, according as the subject of observation by their aid is number, measure, or weight, into—

- A. Counting machines.
- B. Measuring machines.
- C. Copying and drawing machines.
- D. Weighing machines.

And to these may be added a fifth class, in which the functions of the first four are more or less combined, viz.:—

- E. Recording machines.

139. (A.) *Counting Machines.*—The most important as well as the most common of counting machines are *time-keepers*, which count and indicate the numbers of oscillations of bodies which oscillate isochronously (viz., pendulums for clocks, balance-wheels for watches and marine chronometers) so as to measure time. In constructing such machines, the objects to be aimed at are the exact isochronism of the pendulum or balance, and the equable action of the motive power, so that it shall overcome the friction of the mechanism without affecting the rate.

Other counting machines count the oscillations of the beam of a steam-engine, or the revolutions of the cylinder of a gas-meter or of the wheel of a water-meter.

Others perform additions, subtractions, and multiplications, and of these the most elaborate kind (as, e.g., that of Babbage) compute tables of functions by the addition of differences.

140. (B.) *Measuring Machines.*—Measuring machines are pieces of mechanism, by means of which the motion of some body of the nature of an index through some geometrical magnitude, such as a distance or an angle, is connected with some other motion, either equal or greater or smaller in some given ratio, and capable of being more readily compared with some standard of measure.

To this class belong all those astronomical and surveying instruments in which the motion of a line of sight (generally the line of collimation of a telescope) through a given angle is connected with the motion of an index or vernier round a corresponding arc of a graduated circle; also those micrometers in which the advance of the end of a screw of fine pitch is measured by observing the simultaneous arc of rotation of a graduated circle attached to it.

Such micrometers have attained increased importance by the discovery of Whitworth,—that the mechanical magnifying of small distances by a train of screws affords a more accurate means of measurement than optical magnifying by the microscope,—and by the perfection to which that engineer has brought that art of accurate workmanship which is necessary in order to render mechanical magnifying possible.

Amongst measuring machines are included the *platometers* or *planimeters* of Sang, Morin, and Clerk Maxwell, which measure

areas by means of mechanism. The amount of resistance in a measuring machine should be perfectly uniform, and sufficiently great to prevent accidental forces from disturbing the machine, without being so great as to render it inconveniently stiff. To combine these objects requires great accuracy of workmanship, together with strength and rigidity in the structure of the frame and mechanism.

141. (C.) *Copying and Drawing Machines.*—In copying machines for enlarging or reducing drawings there is usually a combination of levers and linkwork connecting a tracing-point, which is moved over the lines of the original figure, with a drawing-point, which draws the copy in such a manner that the velocity ratio of their motions is a given constant quantity, and that the directions of their motions make a constant angle.

Mechanism depending for its principle on the theory of the composition of rotations is used to draw ellipses, epicycloids, epitrochoids, and other curves.

142. (D.) *Weighing Machines.*—In weighing machines the motion of the mechanism is used only for the purpose that its cessation, or its becoming an oscillation about a certain position, may indicate the equilibrium of the forces applied to the machine. Those forces may either be weights, which are to be compared with each other, or forces of other kinds, to be compared directly or indirectly with weights.

The machine for comparing weights which is capable of the most minute accuracy is also the simplest, being the *balance*, in which the equality of two weights is ascertained by their balancing each other at the ends of a lever of equal arms. In the *steelyard*, consisting either of one lever or of a train of levers, the unknown weight has an unchangeable point of application, and is compared with a known weight by shifting the latter along the lever to which it is applied until the machine is balanced; the ratio of the weights is then the reciprocal of the velocity ratio of their points of application. The steelyard is more convenient for weighing very heavy loads than the balance, but is not capable of such minute accuracy.

It is essential to accuracy in balances and steelyards that the friction should be less than the smallest admissible amount of error. To diminish the friction as much as possible, the axes of motion are all *knife-edges*, as they are termed, of steel or hardened iron, resting on hard surfaces of hardened iron or steel for ordinary purposes, and of some hard mineral, such as agate, for scientific purposes.

The weight of a column of fluid is determined by balancing it against a column of fluid whose weight is known, as in the barometer, where the weight of a column of the atmosphere is balanced against that of a column of mercury.

Weights are compared with each other indirectly, and other forces compared with weights, by means of their effects in bending a spring,—a convenient method, but not susceptible of minute accuracy.

The elastic pressure exerted by a fluid may be compared with weight, either by balancing the pressure against the weight of a column of a liquid, or by maintaining a piston in equilibrium against that pressure, by means of a weight pressing it directly, or of a weight acting through a steelyard, or of the elasticity of a spring which has been compared with weights.

143. (E.) *Recording Machines.*—Recording machines may be divided into two classes:—*self-registering instruments*, which, by the aid of clockwork, record measurements either of space or of force, together with the instants of time at which these measurements were made; and *dynamometers*, already mentioned in Chap. II. of this article, which register measurements of force, together with the space through which it has acted, thus recording energy or work.

144. *Working Machines Classed.*—The object or purpose of working machines is to perform useful work; and their classification relatively to their objects and purposes is founded on the kind of useful work which they perform. In this point of view they may be classed as follows:—

- A. Machines for lifting or lowering solid weights.
- B. Machines for the horizontal transport of weights, either combined or not with lifting or lowering.
- C. Machines for projecting solids.
- D. Machines for lifting fluids.
- E. Machines for propelling or projecting fluids.
- F. Machines for dividing bodies.
- G. Machines for shaping bodies by removing portions of them.
- H. Machines for shaping bodies by pressure.
- I. Machines for uniting bodies into fabrics.
- J. Machines for printing.
- K. Machines for producing sound.
- L. Miscellaneous machines.

It is not pretended that the above classification (taken to a considerable extent from the writings of Young and of Babbage) exhausts all kinds of machines; it is brought forward merely as an attempt to introduce method to a certain extent into a subject which would otherwise be exceedingly confused.

145. (A.) *Machines for Lifting and Lowering Solids.*—The most common machines of this class are *capstans*, *cranes*, and *windlasses*.

They are usually worked by manual labour, but sometimes by hydraulic engines, or by steam-engines. The useful resistance, when a load is lifted, being the weight of that load, is in general greater than the effort exerted by the prime mover, so that the mechanism has to be adapted to giving the working-piece a less velocity than the piece to which the effort is applied. In lowering solid loads the weight of the load acts as the effort, and the energy exerted by it is expended in overcoming the friction of a brake in order that the speed of descent may not be excessive.

146. (B.) *Transporting Machines*.—The mechanism of transporting machines consists of two parts:—that by which the resistance is diminished, as the wheels and axles of vehicles; and that by which the resistance is overcome and the load propelled, comprising all kinds of locomotive and propelling machinery. In the present work transporting machines are treated of in the articles relating specially to the lines of conveyance to which they are applied.

147. (C.) *Machines for Projecting Solids*.—This class comprehends all kinds of artillery.

148. (D.) *Machines for Lifting Fluids*.—See HYDROMECHANICS.

149. (E.) *Machines for Propelling or Projecting Fluids*.—See the same article.

150. (F.) *Machines for Dividing Bodies*.—This class comprehends all machines for separating solid masses into parts, whether by digging, cutting, sawing, grinding, tearing, crushing, pounding, pressing out fluids, or otherwise; and whether applied to earth, stones, metals, timber, fruit, grain, fibres, or other materials.

151. (G.) *Machines for Shaping Bodies by Removing Portions of them*.—This class of machines to a certain extent resembles the preceding. It includes machines for cutting, grinding, and polishing blocks of stone into required figures, and for shaping pieces of wood, metal, or other material, whether by *turning*, to produce spherical, cylindrical, and other curved surfaces,—by *boring*, *punching*, *slotting*, or *gouging*, to produce cylindrical, rectangular, or other orifices and grooves,—by *screw-cutting*, by *planing*, by *grinding* and *polishing*, to produce curved or plane surfaces. The most difficult and important of all these operations is to produce a surface truly plane; and the perfecting of this operation by Whitworth is the most important step recently made in *Constructive Mechanics*, or the art of making machines and instruments. Next in point of difficulty may be placed the art of forming the concave reflecting surfaces of great specula for telescopes, such as those of the Herschels, of Lassell, and of Lord Rosse.

152. (H.) *Machines for Shaping Bodies by Pressure* comprehend, amongst others, *rolling-mills* for iron, *steam-hammers*, *wire-drawing* machines, *pin-making* and *nail-making* machines, *coining* and other *stamping* machinery, *brick-making* machines, *presses* for packing and compressing, &c.

153. (I.) *Machines for Uniting Bodies into Fabrics* comprise *spinning* machinery, whether applied to ropes, yarn, or thread, *weaving* machinery of all kinds, *paper-making* machinery, *felt-making* machinery, and *sewing* machinery.

154. (J.) *Machines for Printing* are used to apply either colouring matters or matters for discharging colour to paper, cloth, and other materials.

155. (K.) *Machines for producing Sound*.—See ACOUSTICS and MUSIC.

156. (L.) *Miscellaneous Machines*.—There are numerous machines which perform processes, especially in the preparation of textile fabrics for the market, which it would be almost impossible to class. Examples of such machines will be found by referring to the articles relating to the various branches of manufacture.

#### CHAPTER IV. APPLIED ENERGETICS, OR THEORY OF PRIME MOVERS.

157. *Prime Movers in general—Their Efficiency*.—Prime movers, or receivers of power, are those pieces or combinations of pieces of mechanism which receive motion and force directly from some natural source of energy. The point where the mechanism belonging to the prime mover ends and that belonging to the train for modifying the force and motion begins is somewhat arbitrary; in general, however, the mechanism belonging to the prime mover may be held to include all pieces which regulate or assist in regulating the transmission of energy from the source of energy. Thus, in the ordinary rotative steam-engine, the crank-shaft belongs to the prime mover, because it carries the eccentric which moves the valves and the fly-wheel which stores and restores the periodical excess of energy of the engine, and drives the governor (when there is one) which regulates the admission of steam.

The *useful work* of the prime mover is the energy exerted by it upon that piece which it directly drives; and the ratio which this bears to the energy exerted by the source of energy is the *efficiency* of the prime mover.

It is often convenient to divide the prime mover into sections, and resolve its efficiency into factors, each factor being the efficiency of one of those sections. Thus the efficiency of a steam-engine may be resolved into the following factors:—

*Efficiency of the furnace and boiler*,—being the proportion of the total heat of combustion of the fuel which takes effect in heating and evaporating the water.

*Efficiency of the steam in driving the piston*,—being the proportion of the energy exerted by the steam on the piston (called the *indicated energy* or power, as being measured by an indicator) to the mechanical equivalent of the heat received by the water.

*Efficiency of the mechanism from the piston to the crank-shaft inclusive*,—being the proportion of the effective energy transmitted by the crank-shaft to the indicated energy.

The product of those three factors is the efficiency of the engine as a whole.

In all prime movers the loss of energy may be distinguished into two parts,—one being the unavoidable effect of the circumstances under which the machine necessarily works in the case under consideration; the other the effect of causes which are, or may be, capable of indefinite diminution by practical improvements. Those two parts may be distinguished as *necessary loss* and *waste*.

The efficiency which a prime mover would have under given circumstances if the *waste* of energy were altogether prevented, and the loss reduced to necessary loss alone, is called the *maximum* or the *theoretical efficiency* under the given circumstances.

For some prime movers there is a combination of circumstances which makes the theoretical efficiency greater than any other combination does. The theoretical efficiency under those circumstances is the *absolute maximum efficiency*.

The *duty* of a prime mover is its useful work in some given unit of time, as a second, a minute, an hour, a day. In some cases, such as that of the work of animals, the duty can be ascertained, while the efficiency can only be inferred indirectly or conjecturally from the want of precise data as to the whole energy expended.

158. *Sources of Energy Classified*.—The sources of energy used in practice may be classed as follows:—

- A. Strength of men and animals.
- B. Weight of liquids.
- C. Motion of fluids.
- D. Heat.
- E. Electricity and magnetism.

159. (A.) *Strength of Men and Animals*.—The *mechanical daily duty* of a man or of a beast is the product of three quantities—the effort, the velocity, and the number of units of time per day during which work is continued. It is well known that for each individual man or animal there is a certain set of values of those three quantities which make their product, the daily duty, a maximum, and that any departure from those values diminishes the daily duty. Attempts have been made to represent by a formula the law of this diminution; but they have met with imperfect success. That which agrees on the whole best with the facts is the formula of Maschek, which is as follows:—let  $P_1$  be the effort,  $V_1$  the velocity, and  $T_1$  the time of working per day, which give the maximum daily duty, and let  $P$ ,  $V$ ,  $T$ , be any other set of values of those quantities; then

$$\frac{P}{P_1} + \frac{V}{V_1} + \frac{T}{T_1} = 3 \quad \dots \dots \dots (86).$$

One consequence of this formula is, that the best time of working per day for men, and for all animals, is *one-third part of a day*, or eight hours,—a conclusion in accordance with experience.

The best effort  $P_1$ , and the best velocity  $V_1$ , are much less certain,—the difficulty of determining their true mean values for particular species being rendered very great by the differences, not only between individuals, but between races or varieties of the same species. The following table of values is proposed by Maschek as approximately true:—

| Animals.              | Weighing.<br>lb. | $P_1$ . | $V_1$ .          | $T_1$<br>2400. | $P_1 V_1$ .      | $P_1 V_1 T_1$ . |
|-----------------------|------------------|---------|------------------|----------------|------------------|-----------------|
|                       |                  | lb.     | Feet per second. | Hours per day. | Foot-lb per sec. | Foot-lb.        |
| Man.....              | 150 lb           | 30      | 2.5              | 8              | 75               | 2,160,000       |
| Horse (draught) ..... | 600 lb           | 120     | 4.0              | 8              | 480              | 13,824,000      |
| Ox.....               | 600 lb           | 120     | 2.5              | 8              | 300              | 8,640,000       |
| Ass.....              | 360 lb           | 72?     | 2.5              | 8              | 180              | 5,184,000?      |
| Mule.....             | 500 lb           | 100?    | 3.5              | 8              | 350              | 10,080,000?     |

Of the numbers in this table those for the draught horse are probably the most accurate. For the thoroughbred horse it is certain that the value of  $V_1$  is much greater, and that of  $P_1$  much less, than for the draught horse,—the effect being probably that the *maximum* daily duty  $P_1 V_1 T_1$  is nearly the same; but experimental data are wanting to determine these quantities with precision.

The following table, chiefly extracted from the works of Poncelet and Morin, with the addition of some results of experiments by Lieutenant David Rankine and by the author of this article, shows the daily duty of men and horses under certain specified circumstances:—

|   | P.                              | V.              | T                | PV.                 | PVT.                |
|---|---------------------------------|-----------------|------------------|---------------------|---------------------|
|   | lb.                             | Feet<br>p. sec. | Hours<br>p. day. | Foot-lb<br>per sec. | Foot-lb<br>per day. |
| <b>MAN—</b>   |                                 |                 |                  |                     |                     |

160. *Horizontal Transport.*—When men and animals carry burdens, or draw or propel loads in certain vehicles, it is difficult, and sometimes impossible, to determine the duty performed in foot-pounds of work, because of the uncertainty of the amount in pounds of the resistance overcome. In this case, for the purpose of comparing performances of the same kind with each other, a unit is employed called a *foot-pound of horizontal transport*, meaning the conveying of a load of 1 pound 1 foot horizontally. The following table, compiled from the sources referred to in sect. 159, gives some examples of the daily duty of men and horses in units of horizontal transport, *L* denoting the load in lb, *V* the velocity in feet per second, and *T* the number of seconds per day of working:—

|  | L.              | V.                  | T                 | L.V.                   | LVT.                   |
|--|-----------------|---------------------|-------------------|------------------------|------------------------|
|  | lb.             | Feet per<br>second. | Hours<br>per day. | lb conveyed<br>1 foot. | lb conveyed<br>1 foot. |
| <b>MAN—</b>  |                 |                     |                   |                        |                        |
| 15. Walking unloaded, trans-<br>port of own weight.....  | 140             | 5                   | 10                | 700                    | 25,200,000             |
| Do. do. do.....  | 140             | 6                   | 10                | 840                    | 30,240,000             |
| 16. Wheeling load <i>L</i> in two-<br>wheeled barrow, return-<br>ing empty; $V = \frac{1}{2}$ velocity | 224             | 1.6                 | 10                | 378                    | 13,428,000             |
| 17. Do. one-wheeled barrow, do.  | 135             | 1.6                 | 10                | 225                    | 8,100,000              |

161. (B.) *Weight of Liquids.*—(C.) *Motion of Fluids.*—In water-wheels and other hydraulic engines the weight and motion of a liquid usually act together as sources of energy.

To determine the necessary loss of energy and the theoretical efficiency, we have the following formulæ:—

$$\left. \begin{aligned} &\text{The power or energy exerted per second is} \\ &\quad Q \left( H + \frac{V_1^2}{2g} \right); \\ &\text{the necessary loss—} \\ &\quad Q \cdot \frac{V_2^2}{2g}; \\ &\text{the theoretical effect or useful work per second—} \\ &\quad Q \left( H + \frac{V_1^2 - V_2^2}{2g} \right); \\ &\text{the theoretical efficiency—} \\ &\quad \left( H + \frac{V_1^2 - V_2^2}{2g} \right) \div \left( H + \frac{V_1^2}{2g} \right) \end{aligned} \right\} \quad (87);$$

where *Q* denotes the weight of liquid which acts on the wheel or other engine per second; *H* the vertical fall from the point where the liquid first begins to act directly or indirectly on the wheel or

other engine to the point where it ceases to act; *V*<sub>1</sub> the velocity of the liquid when it begins to act; and *V*<sub>2</sub> the least velocity, when it ceases to act, which will properly discharge the liquid, and prevent its accumulating so as to impede the wheel or engine.

(For details as to the actual efficiency and duty and the construction of hydraulic engines, see *HYDROMECHANICS*.)

In *windmills*, the air, being in motion, presses against and moves four or five radiating vanes or *sails*, whose surfaces are approximately helical, their axis of rotation being parallel, or slightly inclined in a vertical plane, to the direction of the wind. The best form and proportions for windmill sails, as determined experimentally by Smeaton, are as follows (see fig. 36):—

Angle of each sail with the plane of rotation—at DE=18°;

Do. do. do. at BC=7°;

OD=½ of whip OA; bar DE=¼ OA; bar BC=¼ OA; AC=DE.

162. (D.) *Heat.*—In sect. 157 the three factors into which the efficiency of an engine moved by heat can be resolved have already been stated. The efficiency of the furnace and boiler in steam-engines varies from 0.4 to 0.85. It may be considered that the loss of heat to the extent of 0.15 by the chimney is necessary in order to produce a sufficient draught; any loss beyond this is *waste*. The theoretical efficiency of the *steam*, or other *elastic fluid*, which serves as the mechanism for converting heat into mechanical energy, is regulated by a law which will now be explained.

Heat acts on bodies in two ways—to elevate temperature and make the bodies hotter, and to produce mechanical changes. Heat employed in producing mechanical changes disappears or becomes *latent*, as it is termed, and can be reproduced by reversing those mechanical changes. When a cycle of mechanical changes, ending by the restoration of the body to its original condition, produces mechanical energy, heat disappears to an amount equal to that which would be generated by employing the mechanical energy in overcoming friction,—that is to say, a British unit of heat (or one degree Fahr. in one lb of liquid water) for every 772 foot-pounds of energy (being the constant already mentioned in sect. 115 as *Joule's equivalent*). This is called the *conversion of heat into mechanical energy*.

The *efficiency of the fluid* in a heat-engine is the proportion which the heat converted into mechanical energy bears to the whole heat received by the water or other fluid; and the *theoretical or maximum* value of that efficiency depends solely upon the respective temperatures at which the fluid receives heat and rejects the unconverted heat, according to the following law:—let *t*<sub>1</sub> represent the temperature at which the fluid receives heat, and *t*<sub>2</sub> the temperature at which it rejects the unconverted heat, as measured from the *absolute zero*,—that is, from a point 493°·2 Fahr. or 274° C. below the temperature of melting ice (temperatures so measured are called *absolute temperatures*); then the *maximum theoretical efficiency of the water or other fluid in a steam-engine or other heat-engine is*

$$\frac{t_1 - t_2}{t_1} \quad (88).$$

The necessary loss of heat by the fluid is *t*<sub>2</sub>/*t*<sub>1</sub> of the whole heat received by it; and any loss beyond this is *waste*.

The theoretical efficiency of the steam in ordinary steam-engines seldom exceeds ½th; the greatest actual efficiency is about ¼th; the efficiency in good ordinary engines is about 0.1 or 0.08, and in bad and wasteful engines 0.04, or even less. (For details see *STEAM-ENGINE*.)

163. (E.) *Electricity and Magnetism.*—Electricity developed by chemical action in a galvanic battery has been to a small extent used to produce mechanical energy by alternately magnetizing and unmagnetizing soft-iron bars.

The data for determining the actual efficiency of such engines are deficient. Their theoretical efficiency depends on the following law demonstrated by Joule:—

Let *γ*<sub>1</sub> denote the strength of the electric current which would be developed in the conducting wire of the battery if there were no iron bar to be magnetized; *γ*<sub>2</sub> the strength to which the current is reduced by the reaction of the iron bar, tending to induce a contrary current. Then the theoretical efficiency of the engine is

$$\frac{\gamma_1 - \gamma_2}{\gamma_1} \quad (89).$$

The proportion of the energy expended which is *necessarily lost* is *γ*<sub>2</sub>/*γ*<sub>1</sub>, and is employed in producing heat in the conducting circuit. This law is exactly analogous to that of the theoretical efficiency of heat-engines given in equation 88.

There is reason to believe that electromagnetic engines are capable of a higher efficiency than heat-engines; but the greater cost of the materials consumed renders them much less economical commercially (W. J. M. R.)

Fig. 36.

**MECHITHARISTS**, a congregation of Armenian monks, in communion with the church of Rome, which has enjoyed papal recognition since 1712. Its founder Mechithar, or Mechitar da Pietro, a native of Sebaste (Sivas) in Armenia, was born on February 7, 1676; his original name was Manuk, which he exchanged for that by which he was subsequently known ("Comforter") when he entered the cloister of the Holy Cross in his native town. In the pursuit of knowledge he visited various seats of learning in Armenia, and in the years 1691, 1696, and 1699 respectively he attained the office of deacon, priest, and vartabed or doctor in theology. Having removed to Constantinople, he founded there in 1701 a religious institute for the intellectual, moral, and spiritual elevation of his countrymen, and for the cultivation of their language and literature. In 1703 sectarian jealousy obliged him to retire to the Morea, where he ultimately found a settlement at Modon, and built a cloister and church (1706-8). The outbreak of hostilities between the Turks and Venetians in 1715 compelled him to take refuge in Venice, where in 1717 he received from the senate the island of San Lazzaro, which ever since has been the home of his order. Mechithar, who died on April 27, 1749, was the author of a *Grammatica Armenica*, printed in 1770, of an Armenian *Lexicon*, printed in 1744, of an Armenian translation of the Bible, printed in 1734, and of several commentaries on Biblical books. The order of Mechitharists, which, as already mentioned, received formal recognition (from Clement XI.) in 1712, uses the Armenian language and the Syrian rite; its rule resembles the Benedictine, prominent among the duties of its members being the proclamation of the gospel and the diffusion of good literature. They have accumulated at San Lazzaro a large library, specially rich in Armenian MSS.; and their linguistic attainments are considerable. Among their services to the cause of learning may be mentioned, in addition to the preparation of critical texts of the Armenian classics and of the Armenian version of the Bible, the publication in old translations of various works of Ephraem Syrus, Philo, and Eusebius, of which the originals have been lost. There are establishments belonging to the order elsewhere in Italy (Padua), as well as in Russia and Turkey, in Paris, in Austria-Hungary, and in Germany. Of these the most important is that of Vienna, which has existed since 1810, and has become a sort of learned "academy," receiving honorary members even from beyond the pale of the Roman Catholic Church.

**MECHLIN**, or **MALINES**, a city of Belgium, in the province of Antwerp, on the river Dyle, about 14 miles north of Brussels. The general aspect of the town, belted by a fine avenue of trees, with well-built houses, extensive gardens, and broad airy streets and squares of proverbial cleanliness, is pleasing to the eye; there is, however, a lack of life and motion, a repose bordering on stagnation; and the area occupied by the town is much too extensive for the population. Mechlin was for many centuries, and is to this day, the religious metropolis of Flanders, and its monuments and curiosities are in general of a sacred description. Among the most remarkable is the cathedral church of St Rombold or Rombaut, mainly built in the latter half of the 14th century; the square massive tower, rising 300 feet high and bearing four dials, each 48 feet in diameter, is visible from all the country round. The interior proportions of the edifice are grand, and it contains some fine works of art—statues of the apostles, standing against the pillars of the nave, Vandyck's picture of the Crucifixion, the Adoration of the Shepherds, by Erasmus Quellin, and others. The church of St John possesses a celebrated triptych of Rubens, and another by the same master is to be seen at Notre Dame. The "Halle" or

market still retains some vestiges of the splendid palace raised on the site by Charles V. in 1530, and on the chief market-place is a monument erected to Margaret of Austria, daughter of the emperor Maximilian. Mechlin is an archiepiscopal see, occupied by a cardinal, primate of Belgium, deriving his spiritual power from Rome, and quite independent of (at times even openly opposed to) the civil Government. His palace is the headquarters of the Catholic party, and the seat of considerable moral and political influence extending over every parish in the land; the university of Louvain, the Catholic schools, more than four thousand in number, and the great seminary of Mechlin, the nursery of the Belgian priesthood, are entirely under the direction of the archbishop. The industrial activity of the town, formerly very great, has constantly decreased in the present century, and is now almost extinct. The important corporation of weavers was scattered by the political troubles of the 15th and 16th centuries; and the lace trade has gradually been transferred to Brussels and other towns. There still exist a few special manufactures, those of carved oak furniture, straw chairs, and wool and linen tissues being among the foremost; some tanyards and breweries are also to be found, and the means of communication furnished by the Dyle supply a tolerably brisk market in corn, oils, flax, hemp, and hops. As a railway station Mechlin possesses peculiar importance, being a junction of the chief Belgian Government lines and the great central workshop for constructing and repairing the rolling-stock. The population of Mechlin in 1880 was 42,381.

Mechlin appears to have been about the 8th century a mere group of cabins surrounding a noted monastery where St Rombaut, now the patron saint of the town, suffered martyrdom on the 24th of June 775. After having belonged to the first Frankish monarchs, it was given by Pippin the Little to his relative Adon, and passed, at the commencement of the 10th century, under the dominion of the bishops of Liège, in whose name it was governed by the powerful house of Berthold until the year 1333. When this family became extinct, Mechlin and the surrounding district were divided in two portions and sold by the bishops to the duke of Brabant and the count of Flanders, the former of whom, ten years later, once more united the whole territory under his own sway. By the marriage of Margaret of Brabant with Philip the Bold, Mechlin was brought under the sceptre of the house of Burgundy, whose fate it shared from that time. Stormed by the French in 1572, by the prince of Orange in 1578, by the English in 1580, the town suffered much during the wars of the 17th and 18th centuries. Napoleon I. had its fortifications razed in 1804, and made it the capital of the French "Département des deux Nèthes" until 1814, when it was comprised in the kingdom of the Netherlands, and it finally became part of Belgium in 1830.

**MECKLENBURG**, a territory in North Germany, on the Baltic Sea, extending from 53° 4' to 54° 24' N. lat., and from 10° 35' to 13° 57' E. long., corresponds with tolerable closeness to the old lower Saxon province of the same name, and is now unequally divided into the two grand-duchies of Mecklenburg-Schwerin and Mecklenburg-Strelitz. These are so closely related in history, political organization, natural features, and general development that it is convenient to treat them in a single article.

**MECKLENBURG-SCHWERIN**, the seventh state of the German empire in size and the eighth in population, is bounded on the N. by the Baltic Sea, on the W. by the principality of Ratzeburg and Lauenburg, on the S. by Brandenburg and Hanover, and on the E. by Pomerania and Mecklenburg-Strelitz. It embraces the duchies of Schwerin and Güstrow, the district of Rostock, the principality of Schwerin, and the barony of Wismar, besides several small "enclaves" in the adjacent territories. Its total area is about 5117 square miles.

**MECKLENBURG-STRELITZ**, the eleventh state of the German empire in area and the nineteenth in population, consists of two detached parts, the duchy of Strelitz on the east of Mecklenburg-Schwerin and the principality of

Ratzeburg on the west. The first of these is bounded by Mecklenburg-Schwerin, Pomerania, and Brandenburg, the second by Mecklenburg-Schwerin, Lauenburg, and the territory of the free town of Lübeck. Their joint area is 1126 square miles.

Mecklenburg lies wholly within the great North-European plain, and its flat surface is interrupted only by one range of low hills, intersecting the country from south-east to north-west, and forming the watershed between the Baltic Sea and the Elbe. Its highest point, the Helpter Berg, is 580 feet above the sea-level. The coast-line runs for 65 miles along the Baltic (without including indentations), for the most part in flat sandy stretches covered with dunes. The chief inlets are the bays of Wismar, Grosse Wiek, Salzhaff, and Kroy, and the roads of Warnemünde. The rivers are numerous though small; most of them are affluents of the Elbe, which itself traverses a small portion of Mecklenburg. Several of the streams are navigable, and the facilities for inland water traffic are increased by a tolerably extensive system of canals. Lakes are very numerous; about four hundred of fair size, covering an area of 500 square miles, are reckoned in the two duchies. The largest is Lake Müritz, 52 square miles in extent. The climate on the whole resembles that of Great Britain, but the winters are generally more severe; the mean annual temperature is 48° F., and the annual rainfall is about 28 inches. Although there are long stretches of marshy moorland along the coast, the soil is on the whole productive. According to the official returns of 1878, about 57 per cent. of the total area of Mecklenburg-Schwerin consisted of cultivated land, 17 per cent. of forest, and 13 per cent. of heath and pasture. In Mecklenburg-Strelitz the corresponding figures were 48, 20, and 9 per cent. Agriculture is by far the most important industry in both duchies. The following table shows the areas and products of the chief crops in 1880:—

| Crops.        | Mecklenburg-Schwerin. |           | Mecklenburg-Strelitz. |         |
|---------------|-----------------------|-----------|-----------------------|---------|
|               | Acres.                | Tons.     | Acres.                | Tons.   |
| Rye.....      | 411,627               | 243,818   | 68,530                | 29,619  |
| Oats.....     | 285,257               | 188,166   | 49,422                | 26,743  |
| Wheat.....    | 108,550               | 43,420    | 26,240                | 93,378  |
| Barley.....   | 44,687                | 33,487    | 10,722                | 7,244   |
| Potatoes..... | 92,942                | 345,233   | 16,440                | 70,537  |
| Hay.....      | 259,497               | 333,737   | 46,805                | 93,464  |
| Totals.....   | 1,202,560             | 1,187,861 | 218,159               | 320,985 |

Besides these, smaller areas are devoted to maize, buck-wheat, pease, rape, hemp, flax, hops, and tobacco. The extensive pastures support large herds of sheep and cattle, including a noteworthy breed of merino sheep. The horses of Mecklenburg are of a fine sturdy quality, and are highly esteemed in Germany. In 1878 the two duchies contained 100,651 horses, 315,712 cattle, and 1,321,916 sheep. Red deer, wild swine, and various other kinds of game are found in the forests. The manufactures of Mecklenburg are of little importance. Its industrial establishments include a few iron foundries, wool-spinning mills, carriage and machine factories, dye-works, tanneries, brick-fields, soap-works, breweries, distilleries, numerous limekilns and tar-boiling works, tobacco and cigar factories, and about eight hundred mills of various kinds. Mining is also insignificant, though a fair variety of minerals is represented in the district. Amber is found on and near the Baltic coast. Trade, mainly confined to the larger duchy, is tolerably active. Rostock, Warnemünde, and Wismar are the principal commercial centres. The chief exports are grain and other agricultural produce, live stock, spirits, wood, and wool; the chief imports are colonial produce, iron, coal, salt, wine, beer, and tobacco. The horse and

wool markets of Mecklenburg are largely attended by buyers from various parts of Germany. Fishing is carried on extensively in the numerous inland lakes. Within the last decade the mercantile fleet of Mecklenburg-Schwerin has doubled the number and quadrupled the tonnage of its ships, these consisting in 1881 of 370 sailing vessels and 11 steamers, with an aggregate burden of 112,388 tons. Mecklenburg-Strelitz has no seaboard.

Mecklenburg-Schwerin and Mecklenburg-Strelitz are both limited monarchies under grand-dukes, who are hereditary in the male line. The reigning families are closely related, and possess mutual rights of succession; should both families become extinct, their possessions pass to Prussia. The constitution, which is common to both the duchies, exhibits few traces of the liberal tendency of modern politics. The temporary modifications brought about by the agitation of 1848 were quickly rescinded, and matters returned to the old semi-feudal arrangements, which deprive the bulk of the people of all share in the government. The constitution as it now exists is based upon an agreement made between the duke of Mecklenburg-Schwerin and his estates in 1755, and adopted in the same year by Mecklenburg-Strelitz. The Landes-Union, or common assembly of the two duchies, consists of representatives of the Ritterschaft, or landed proprietors, and of the Landschaft, which embraces forty-seven towns. The peasantry is unrepresented, and the principality of Ratzeburg, in Mecklenburg-Strelitz, is governed directly by the grand-duke. The Landes-Union meets once annually, alternating between Sternberg and Malchin. When not sitting it is represented by a committee of nine members. Distinct from the Landes-Union are the convocation diet and the deputation diet, which are assemblies of the estates of one or other duchy for special business. In Mecklenburg-Schwerin the executive is placed in the hands of four ministers, holding the portfolios of foreign affairs, domestic affairs, finance, and justice (including education and religion). In Mecklenburg-Strelitz there is one minister, who is aided by a small council. In both duchies the military administration is in the hands of the crown. Mecklenburg-Schwerin has two votes in the federal council of the German empire, and sends six members to the imperial diet, while the smaller duchy has one representative in each assembly. As no official budget is published in either duchy, it is impossible to give accurate details of their financial position. In Mecklenburg-Schwerin it is usual to distinguish three branches of revenue, one under the control of the sovereign, one under the joint control of the sovereign and estates, and the third (of small amount) under the sole management of the estates. The income under the first heading is derived from the royal domains, the ordinary taxes, and special votes for special purposes, and amounts to about £600,000. With this sum are defrayed the ordinary expenses of government, including the annual contribution to the imperial treasury. The revenue under the second head is about £100,000. The public debt in 1880 amounted to £1,100,000. The revenues of Mecklenburg-Strelitz are unknown; its debt is estimated at about £300,000. The private income of the duke, derived from the royal domains, makes him one of the richest princes in Germany. The duchies of Mecklenburg contribute three regiments of infantry, a battalion of rifles, two regiments of dragoons, and four batteries of field artillery to the imperial army.

The educational institutions partake of the high character common to those of the German empire. The two duchies contain nine gymnasia, seven "Realschulen," three normal schools, and an adequate number of schools of a lower grade. There is a university at Rostock, which in 1882 had a teaching staff of 36 professors and an attend-

ance of about 250 students. In 1880-81 only 0.56 per cent. of the recruits in Mecklenburg-Schwerin were unable to read and write their names, while all the recruits in Mecklenburg-Strelitz were able to do both. The predominant confession in Mecklenburg is the Lutheran, which is professed by both the grand-dukes. The proportion of Roman Catholics, Jews, and members of the Reformed Church is insignificant. The ultimate spiritual authority is exercised by consistories at Schwerin and Strelitz. Mecklenburg also contains a fair share of learned societies and benevolent institutions. The supreme court of appeal for both duchies, in all criminal and civil cases, is at Rostock.

The population of Mecklenburg-Schwerin in 1861 was 548,449; in 1871, 557,707; in 1875, 553,785; and in 1880, 577,055. The capital is Schwerin (30,146 inhabitants), but the most important town is Rostock (36,967 inhabitants). The population of Mecklenburg-Strelitz in 1861 was 99,060; in 1871, 96,982; in 1875, 95,673; in 1880, 100,269. The chief town is Neu-Strelitz. About 71 per cent. of the inhabitants are engaged in agricultural pursuits; and 62 per cent. are classed as belonging to the rural population, i.e., as living in communities with less than 2000 inhabitants. The peasantry of Mecklenburg still retain numerous traces of their Slavonic origin, especially in their speech, but their peculiarities have been much modified by amalgamation with the German colonists who settled within this district at various times. The townspeople and nobility are almost wholly of Saxon strain. The slow rate of increase in the population of Mecklenburg is chiefly accounted for by the constant stream of emigration. Between 1870 and 1880 the two duchies contributed in the highest proportion to the emigration from Germany. Out of 595,151 German emigrants who sailed from Bremen, Hamburg, Stettin, and Antwerp within that period, 24,870 came from Mecklenburg-Schwerin and 2481 from Mecklenburg-Strelitz, representing respectively 4.38 and 2.52 per 1000 inhabitants as the yearly average. Probably another cause of the slow growth of population is to be sought for in the difficulties thrown in the way of the marriage of the peasants by the semi-feudal character of their tenure. It is a significant fact that in 1880 the proportion of illegitimate births in the two duchies amounted to 14 per cent. as compared with 9 per cent. in the entire German empire.

*History.*—The Vandals, who in the time of Tacitus occupied the region now known as Mecklenburg, were succeeded in the 6th century by a Slavonic race. Though partly conquered by Charlemagne in 789, this people soon regained their independence, and long offered a successful resistance to all attempts on the part of the German emperors to overcome and Christianize them. At last, in 1160, Duke Henry of Saxony made himself master of the country. The native prince was, however, permitted to retain his sovereignty, and has transmitted to his descendants and successors of the present day the distinction of being the only ruling princes of Slavonic origin in Germany. In 1160 he was raised by the emperor Frederick I. to the dignity of a prince of the empire. From 1202 till 1227 Mecklenburg was under Danish supremacy; and in 1229, two years after its restoration to Germany, there occurred the first of a long series of divisions of the territory, which, with subsequent reunions, constitute so much of its complicated history. In 1348 Charles IV. made Mecklenburg a duchy. In 1523 the trials and commotions springing from the rivalry and jealousy of two joint rulers incited the prelates, nobility, and burghers to form a union among themselves, the effects of which are visible to the present day,—most prominently in the existence of the common Landes-Union. The Reformation was welcomed by the inhabitants of Mecklenburg in 1524; and about 1555 nearly all the monasteries were suppressed. In 1621, when a new partition took place, the town of Rostock "with its university and high court" was declared to be held in common. The diet also retained its joint character, and henceforth alternated between Sternberg and Malchin.

In the Thirty Years' War both Mecklenburg-Schwerin and Mecklenburg-Güstrow—as the parts were then called—incurred the suspicion of the emperor, who secretly sold them to Wallenstein, and expelled the dukes in his behalf. They were reinstated, how-

ever, by Gustavus Adolphus, and at the peace of Prague in 1635 they both made their peace with the emperor. At the peace of Westphalia Rostock and some other parts of Mecklenburg territory were given in pledge to Sweden, and they were not redeemed till 1803. The sufferings of the Mecklenburg peasantry during the Thirty Years' War were exceeded in no other part of sorely-tryed Germany. Most were reduced to serfdom through poverty; in some cases whole villages utterly vanished. In 1695 the Mecklenburg-Güstrow line became extinct; and, after some contention between the brother and the nephew of the last duke of Mecklenburg-Schwerin for the vacant succession, the "Hamburg Division" (March 8, 1701) apportioned to each shares that are represented by the present duchies. The affixes Schwerin and Strelitz are derived from the capital towns of the two dukes.

Mecklenburg-Schwerin began its new independent existence by a series of constitutional struggles between its nobility and its rulers. The heavy debt incurred by Charles Leopold, who had joined Russia in a war against Sweden, brought matters to such a pitch that in 1728 the emperor Charles VI. deposed the duke in favour of his brother Christian Louis. Under this prince, the "Rostock Contract," which is still the basis of the constitution, was framed in 1755. During the Seven Years' War Mecklenburg-Schwerin assumed a hostile attitude towards Frederick the Great, and was in consequence occupied by Prussian troops. In 1806 it was overrun by the French, and in 1808 it joined the confederation of the Rhine. The duke, however, though he assisted Napoleon in 1812, was the first member of the confederation to renounce it, and in the following year his troops fought against France and Denmark. On joining the Germanic confederation he assumed the title of grand-duke, with the style of royal highness. In and after 1848 the duchy witnessed a considerable agitation in favour of a new and more liberal constitution, but the subsequent reaction rescinded all the concessions that had been made, and reduced matters to their former feudal condition. In 1819 and 1820 serfdom and personal bondage were abolished, and various slight ameliorations of the state of the peasantry have since been introduced.

Mecklenburg-Strelitz adopted the constitution of the sister duchy by an "Agnitions-Act" in 1755. In 1806 it was spared the infliction of a French occupation through the interest of the king of Bavaria; but in 1813 it was mulcted in the sum of two million thalers for the French army. In 1808 it entered the Rhenish confederation, but repudiated it in 1813 and joined the alliance against Napoleon. In 1815 the duke assumed the title of grand-duke.

#### MEDALS. See NUMISMATICS.

MEDEA, the daughter of Æetes, king of the Colchians, who were believed to be of Egyptian descent (Herod., ii. 104), and are said to have found a settlement on the east of the Euxine and to the south of the Caucasus. Medea was one of the "wise women" (witches or sorceresses) of antiquity, and perhaps, like Helen, was a human embodiment of some goddess connected with Eastern element-worship, possibly with Hera. For the story of her love for Jason the Argonaut, and of the revenge she took for his desertion of her for another bride, a Corinthian princess, Glauce, daughter of Creon, see ARGONAUTS and JASON. A more interesting inquiry is the origin of the tale, and its connexion with solar myths.

The legend of the Argonautic expedition is a very ancient one. It is alluded to in the *Odyssey* (xii. 70), in more than one passage of Æschylus,<sup>1</sup> and is given at some length in the fourth Pythian ode of Pindar, the close agreement of which with the Alexandrine compilation by Apollonius Rhodius, entitled *Argonautica*, in four books, shows that, according to the general law of mythology, the main features of the legend differed but little. The original story, it is probable, was contained in a still older epic poem called *ἡ Μυρὰς ποίησις*, the authorship of which was ascribed to Prodicus of Phocæa.<sup>2</sup>

The "Golden Fleece," in quest of which the adventurers

<sup>1</sup> He alludes to Phineus and the *Lemnia facinora* (*Eum.* 50; *Cho.* 620), and there were plays composed by him on both these subjects.

<sup>2</sup> Pausan., iv. 33, 7. He quotes from it two hexameter verses in x. 28, 2.

made a voyage from the home of Jason, Iolchus in the Thessalian Magnesia, is virtually identical with the fiery robe which Medea prepared for her rival Glauce, the new bride, with the Homeric "ægis," and with the garment smeared with phosphorus which was sent by Deianira to Hercules, and burst into a flame when brought near to a sacrificial fire.<sup>1</sup> Jason, as the story went, was not allowed by the guardian of the fleece, King Æetes, to approach it till he had performed a certain task in putting to the yoke fire-breathing bulls, which he effected by the aid of Medea. The bull is a well-known symbol of the sun, and it occurs in the bull-slaying group representing the Persian sun-god Mithras. Again, the slaying of a father by a son (the old sun killed by the new one) is seen alike in Œdipus having caused the death of his father Laius, in Æson, the father of Jason, having been restored to life by the magic arts of Medea, and in Pelias having been killed and boiled in a caldron by his own daughters at the instigation of the sorceress. Lastly, the legend that Medea was herself the granddaughter of the Sun, and that she escaped in a car drawn by flying dragons, given to her for safety by her grandsire,<sup>2</sup> equally tends to prove that the whole story is of solar origin, and can be explained on that theory alone.

This, indeed, has been well stated by Sir G. W. Cox.<sup>3</sup> The "dragon chariot is simply the chariot of Indra, Helios, and Achilles; and it is drawn by dragons because the word denoted simply beings of keen sight, and was naturally applied to the creatures which may be supposed to bear the sun across the heaven."

In all these legends about the sun the performance of certain imposed "toils" or labours is included, the idea expressed being the hard necessity of the sun going his daily course in the appointed time in spite of thickening storm-clouds and opposing powers of darkness, through which he has to fight his way, both visibly above and invisibly underneath the earth. Thus Hercules has his twelve labours (the number corresponding to the lunar months), while Jason is not only required by his uncle King Pelias to bring the golden fleece, but is commanded by Æetes to tame the bulls as a condition of obtaining it. The name *Μήδεα* may possibly be referred to *μήδεσθαι*, "to care for," as Jason may contain the root *ἰάσθαι*, "to heal," which is the meaning that Pindar attaches to it,<sup>4</sup> or to *ἰών*, the violet-coloured dawn, as in Iocaste, Iamos, and Iolaus.<sup>5</sup> In his relation to the snake, which guarded the fleece, and to the dragons' teeth which he sowed on the ground ploughed by the fiery bulls, compared with the serpent entwining the staff of the healing god Asclepius, we see that almost invariable connexion that subsists between solar and phallic worship.<sup>6</sup> This view is confirmed by the "ship Argo," one of the many sexual symbols of cup-shaped and boat-like form.<sup>7</sup> It is the "ship" which was the Teutonic symbol of the goddess Isis.<sup>8</sup>

The existing literature on the love of Medea for Jason shows how popular was the story in antiquity for its pathos and its sentimentality. Thus the *Medea* of Euripides was rendered by Ennius; Neophron of Sicily and Melanthius<sup>9</sup> wrote plays of the same name; we have the long and fine Pythian ode of Pindar, already referred to, the touching epistle "Medea Jasoni" in the *Heroides* of Ovid, and the interesting, beautiful, and too little read *Argonautica* of Apollonius.

Of course, the similarity of the names *Μῆδοι* and *Μήδεα* led to

etymological speculations on the identity of the nomenclature, and one Medus, a son of Medea, was believed to have been an eponym hero.<sup>10</sup> The author of the compilation known as Hesiod's *Theogony* says that Medeus was a son of Medea by Jason,<sup>11</sup> and was brought up, as Jason himself had been, by Chiron in the mountains. Euripides assigns but two children to Medea and Jason,<sup>12</sup> and Apollodorus<sup>13</sup> gives their names as Mermnerus and Pheres.

MEDELLIN, a town of Colombia, South America, capital of the state of Antioquia, is situated at a height of 4845 feet above the sea, in the valley of the Rio Porce, a right-hand tributary of the Rio Cauca, and, though 100 miles from the confluence, not more than 16 miles east from the valley of the larger stream. It is a clean and well-built place, but has no public buildings of note. Though the population is estimated at 14,000, there is no great activity except on the market days, twice a week, when the buyers and sellers flock in from the country. See Fr. von Schenck in *Petermann's Mittheil.*, 1880.

MEDFORD, a town of the United States, in Middlesex county, Massachusetts, at the head of navigation on Mystic river, and 5 miles north-west of Boston by a branch of the Boston and Maine Railroad. It is a busy place, with a considerable variety of manufactures—woollens, carpets, buttons, bricks, leather, &c. Tufts College, situated near the town on Walnut Hill, was founded by the Universalists in 1853, and named in honour of Charles Tufts, the donor of the 70 acres occupied by the building and its grounds. The endowment amounts to more than \$1,000,000. The population of Medford was 5717 in 1870 and 7537 in 1880.

MEDHURST, WALTER HENRY (1796–1857), one of the most distinguished Protestant missionaries to the Chinese, was born in London in 1796. His education began at St Paul's Cathedral school. As he grew up, he learned the business of a printer; and, having become interested in missions to the heathen, he sailed in 1816 for the London Missionary Society's station at Malacca, which was likely to be a great printing-centre. His linguistic powers soon showed themselves. He became proficient in Malay, in a knowledge of the written characters of Chinese, and in the colloquial use of more than one of its dialects. He was ordained at Malacca in 1819, and was in all missionary labours "more abundant,"—first at Penang, then at Batavia, and finally at Shanghai. To give only the names of his various works, some in English, some in Chinese, would take a considerable space. A dictionary of one of the Fuh-Kien dialects is still valuable; and his Chinese-English and English-Chinese dictionaries (Batavia, 1842) are more complete and reliable than any earlier or later works of the same kind. After the conclusion of the first English war with China he removed to Shanghai in 1843, and there he continued till 1856, laying the foundations, broad and deep, of a successful mission. His principal labour for several years, as one of a committee of delegates of whom he was *facile princeps*, was in the revision of existing Chinese versions of the Sacred Scriptures. The result was what should be called a new version of the Bible, marvellously correct in idiom, and faithful to the meaning of the original. The university of New York conferred upon him in 1843 the degree of D.D. Medhurst left Shanghai in 1856, with several members of his family, to try the effect of a visit to England for his failing health. He died, however, two days after reaching London, on the 24th January next year. Strong, sprightly, versatile, and genial, he was a man of extraordinary gifts and generous soul. No efforts (and many were made) could draw him from his devotion to the work of missions.

**MEDICAL JURISPRUDENCE**, or, as it is now more usually termed, **FORENSIC MEDICINE**, is that branch of state medicine which treats of the application of medical knowledge to the purposes of the law. The term medical jurisprudence, though sanctioned by long usage, is not an appropriate one; since the subject is, strictly speaking, a branch of medicine rather than of jurisprudence; it does not properly include sanitation or **HYGIENE** (*q.v.*), both this and medical jurisprudence proper being distinct branches of state medicine. The connexion between medicine and the law was perceived long before medical jurisprudence was recognized, or had obtained a distinct appellation. It first took its rise in Germany, and subsequently, but more tardily, received recognition in Great Britain.

Forensic medicine, or medical jurisprudence proper as distinguished from hygiene, embraces all those questions which bring the medical man into contact with the law, and embraces (1) questions affecting the civil rights of individuals, and (2) injuries to the person.

### I. QUESTIONS AFFECTING THE CIVIL OR SOCIAL RIGHTS OF INDIVIDUALS.

1. *Development of the Human Frame.*—The development of the physical and mental powers of the human being is a matter of the highest importance, and is a factor of great consequence in determining criminal responsibility, civil responsibility, or the power of giving validity to civil contracts, and in determining the personal identity of a living person or of a corpse. Human life is usually divided into the five periods of *infancy*, *childhood*, *youth*, *manhood*, and *old age*. Some writers increase the number of these, unnecessarily, to seven periods, without any practical advantage.

*Infancy* is the period from birth till the first or milk set of teeth begin to be shed—usually about the seventh year. During this period the body increases in size and stature more, relatively, than at any other period of existence; and the mental faculties undergo great development. The milk teeth, twenty in number, are evolved in a definite order, beginning with the central incisors at about six months, and ending with the second molars about the termination of the second year. From the size and stature of the body, the development of the teeth, and the more or less advanced state of ossification or solidification of the bony skeleton, conclusions may be drawn as to the probable age of the infant.

*Childhood* extends from the commencement of the shedding of the milk teeth to the age of puberty—usually from the seventh to the fourteenth or fifteenth year. During this period the body expands, as well as the bony structures, without any clearly marked difference in structure being observable between the sexes except as regards the genitals, so that it is impossible to distinguish absolutely between the male and the female skeleton during this period. The milk-teeth are shed, and are replaced by the second or permanent set, thirty-two in number, though these do not usually all make their appearance during childhood. Marked differences between the proclivities of the sexes are noticeable even at an early period of childhood, and long before the characteristic functions begin to be developed.

*Youth* is marked at its commencement by the changes which occur at puberty—the development of the genitals in both sexes, the appearance of hair on the genitals, the appearance of a beard in the male, the development of the breasts in the female, the appearance of the monthly flow in the female, and the ability to secrete semen in the male. Marked mental changes now occur, and the generative functions are perfected. Youth terminates at the age

of legal majority, twenty-one years; or perhaps the period ought to be extended to twenty-five years of age, as it is with some nations.

*Manhood* (or *Womanhood*) is the period of perfection of all the bodily and mental powers. It ceases in woman with the cessation of the monthly flow at about forty-five years of age; but in man it often extends to a much later period of life.

*Old Age* begins with the decay of the bodily and mental faculties, and is characterized by wrinkling of the skin, loss of the teeth, whitening of the hair, and feebleness of the limbs. In its later stages decay of the mental faculties, deafness, obscurity or loss of vision, and bowing of the spine are added.

2. *Duration of Human Life.*—The chances of human life form an important subject of inquiry, which has been elucidated by the labours of Price, Milne, Farr, and others; and on deductions from comparisons of birth and death rates is founded the system of annuities, insurance against loss in sickness, and the insurance of lives. Since the establishment of compulsory registration of deaths, our knowledge of the ordinary and extraordinary chances of human life has been much extended, and surer data are now available for calculations of probabilities of life, of survivorships, and of the payments which ought to be made in benefit clubs. See **INSURANCE** and **LONGEVITY**.

3. *Personal Identity.*—It might be imagined that there is little danger, with the exercise of ordinary care, of mistaking one person for another; but the remarkable case of the Tichborne claimant, and some other less-known but perhaps equally singular instances, have demonstrated that mistakes as to the identity of individuals are easily made, and are more frequent than is commonly supposed. Where the identity has to be established or disproved after long absence, exposure to foreign climates and great hardships, wounds, &c., the problem is often one of extreme difficulty. The data for identifying a person are individual and family likeness, stature, the colour of the eyes, peculiarities of garb and manner, recollection of antecedent events, but more especially marks on the person either congenital or acquired. Such are *naevi* or mother's marks, scars, and disunited or badly united fractures, known to have existed upon the missing person. An accurate solution of the question is, nevertheless, often a matter of the greatest difficulty.

4. *Marriage.*—Under this head the medical jurist has to deal principally with the nubile age, viewed in the light of nature and according to legislative enactments, and with such physical circumstances as affect the legality of marriages, or justify divorce.

In Great Britain the age at which the sexes are first capable of propagating the species is later than in more southern climes. Ordinarily it does not occur before fifteen years of age for the male and fourteen for the female; exceptionally, however, it occurs at the ages of thirteen and of twelve (or even less) respectively in the male and female. By legislative enactment, nevertheless, parents and guardians may, in England at all events, forbid the marriage of young people till the age of legal majority. The only physical circumstances which in Great Britain form a bar to marriage are physical inability to consummate, and the insanity of one of the parties at the time of marriage. Both those circumstances have been pleaded and sustained in the law courts. In other countries minor physical circumstances, as disease, are held to invalidate marriage.

5. *Impotence and Sterility.*—These may arise from organic or from functional causes,—the former being alone irremediable, and as such taken cognizance of by the law courts. On this subject it is unnecessary to enlarge here.

6. *Pregnancy*.—This subject presents one of the widest fields for medico-legal evidence. The limits of age between which it is possible, the limits of utero-gestation, and the signs of pregnancy may all in turn be the subjects of investigation.

The limits of age between which pregnancy is possible are usually fixed by the appearance and cessation of the monthly flow; and these ordinarily begin about fourteen and cease at forty-five years of age. Exceptionally they appear as early as the tenth year, and may not cease till the end of the fifth decade of life. Cases, however, have occurred where a woman has conceived before menstruating; and a few doubtful cases of conception are recorded in women upwards of fifty, or even sixty, years of age. The general fact of pregnancy being limited by the age of puberty on the one hand and the cessation of the monthly flow—or fifty years as the extreme limit of age—must be accepted as the safest guide in practice.

The limits of utero-gestation are not in England fixed by legislation. The French code fixes the extreme limit of three hundred days. The ordinary period is forty weeks and a half, or two hundred and eighty-three days from the cessation of the last monthly flux. The limit of three hundred days, as fixed by the French code, is perhaps never exceeded, if ever reached. The uncertainty of females in fixing the exact date of conception has given rise to the discrepant opinions of physiologists on the subject. It is well known, however, that among the higher animals the period is not a precise one; and impregnation and conception are doubtless not necessarily coincident.

The signs of pregnancy are of the utmost importance to the medical jurist. He may be called upon to pronounce upon the virtue of a female, to sustain or rebut a plea for divorce, to determine whether a capital sentence shall be carried out, or to determine whether it is probable that an heir will be born to an estate. Should he err in his judgment—and mistakes are very possible in the earlier months of utero-gestation—he may commit a grievous wrong. Medical jurists are in the habit of classifying the signs of pregnancy as uncertain or certain; it is the former which are most regarded by the public, but the latter are alone of probative value to the jurist. The usual and uncertain signs are the cessation of the monthly flow, nausea, sickness, a darkening of the areola and the formation of a secondary areola around the nipple, enlargement of the breasts, increased size of the abdomen, the formation of a tumour in the womb, quickening, and the motions of the foetus. There are also other minor signs of less importance. The certain signs are the uterine souffle, which is a peculiar soft sound heard over the abdomen, and synchronous with the maternal pulse; ballottement, or the examination for a floating tumour in the abdomen between the fifth and eighth months of pregnancy; and the pulsations of the foetal heart, heard by means of the stethoscope. These pulsations are much quicker than, and not synchronous with, the maternal pulse. This is the only indubitable sign of pregnancy. It is inapplicable before the fourth month of gestation.

7. *Parturition*.—The imminence of the process of parturition is of comparatively little interest to the medical jurist; but the signs of recent delivery are all-important. These signs are the bruised, swollen, and lacerated state of the external genitals, relaxation and dilatation of the vagina and womb, the existence of a peculiar vaginal discharge known as the lochia, a relaxed and fissured condition of the abdominal walls, a peculiar aspect of the countenance, and the distended state of the breasts due to the secretion of milk. The lochial discharge is the most characteristic sign. All the signs may disappear within ten days of delivery, though this is not usual.

Connected with parturition, the question of *viability* of the child is not unimportant. After the intra-uterine age of seven months is reached a child is certainly viable. The period at which the foetus becomes viable cannot be stated with certainty; but five calendar months, or one hundred and fifty days, is perhaps the nearest approximation which can be made. The viability of a child is judged by its size and weight, its general state of development, the state of the skin, hair, and nails, its strength or feebleness, the ability to cry, and its power of taking maternal nourishment. The question of viability has important bearings upon the crime of infanticide, and the succession to property.

The subject of *superfoetation*, or the possibility of two conceptions having occurred resulting in the birth of twins with a considerable intervening interval, is a very obscure one, and has given rise to much controversy,—its existence being affirmed by some medical jurists, and denied by others. There is much, however (*e.g.*, the existence of a double or bifid womb), to countenance the view that a double conception is possible.

In the curious case of a man marrying a woman having possession of an estate of inheritance, and by her having issue born alive and capable of inheriting her estate, the man on the death of his wife holds her lands for life as a tenant by the “curtesy” of England. Here the meaning of “born alive” is different from the meaning of the same expression as used respecting infanticide. In questions of tenancy by the curtesy it has been decided that any kind of motion of the child, as a twitching and tremulous motion of the lips, is sufficient evidence of live-birth. As regards infanticide, proof of a conclusive separate existence of the child is demanded before live-birth is admitted.

8. *Monsters and Hermaphrodites*.—To destroy any living human birth, however unlike a human creature it may be, is to commit a crime. Blackstone states that a monster which hath not the shape of mankind hath no inheritable blood; but the law has not defined a monster, nor what constitutes a human form. The same author states that if, in spite of deformity, the product of birth has human shape, it may be an heir. Hermaphrodites are beings with malformations of the sexual organs, simulating a double sex. Physiologists do not admit, however, the existence of true hermaphrodites with double perfect organs, capable of performing the functions of both sexes.

9. *Paternity and Affiliation*.—These are often matters of great doubt. A considerable time may elapse between the absence or death of a father and the birth of his reputed child. As has already been said, three hundred days is the utmost limit to which physiologists would extend the period of utero-gestation. This subject involves questions respecting children born during a second marriage of the mother, posthumous children, bastardy, and alleged cases of posthumous children.

10. *Presumption of Survivorship*.—When two or more persons perish by a common accident, when a mother and her new-born child are found dead, and in a few analogous cases, important civil rights may depend upon the question which lived the longest; and great ingenuity has been displayed in elucidating the disputes which have arisen in the law courts in such cases.

11. *Maladies Exempting from Discharge of Public Duties* frequently demand the attention of the medical man. He may be called upon to decide whether a man is able to undertake military or naval service, to act as a juryman without serious risk to life or health, or to attend as a witness at a trial. An endeavour to give a fearless and honest certificate should animate the medical man in the discharge of this delicate duty.

12. *Feigned and Simulated Diseases* often require much

skill and acuteness in order to detect the imposture. Where there is reason to suppose that a disease is simulated, much caution as to procedure is also required.

13. *Insanity or Mental Alienation*.—This subject presents an enormous field to the medical jurist. A medical man may be required to give evidence in any of the law courts, civil, criminal, or ecclesiastical, before commissions *de lunatico inquirendo*, or before a magistrate, as to the sanity or insanity of an individual; and he may have to sign certificates of unsoundness of mind with the view of providing for the safe custody and proper treatment of a lunatic. Hence he must be familiar with the chief forms of insanity (see *INSANITY*), and be able to distinguish and treat each of these. He will also be required to detect feigned insanity, and to examine persons charged with crime with the view of preventing real lunatics from being treated as criminals.

The terms "unsoundness of mind," applied to the condition of the mind itself, and "*non compos mentis*" to the person whose mind is affected, are legal terms applied to insanity. Lawyers have disputed as to whether imbecility should or should not be included under the head of insanity; but medical men include under this category all disorders or defects of the mind which disqualify a person for managing his affairs, and entering into a binding contract, or which render the individual morally irresponsible for his or her otherwise criminal actions. There is good legal authority for recognizing four forms of unsoundness of mind—*idiocy, dementia, mania, and monomania*.

The chief questions respecting unsoundness of mind which present themselves to the medical jurist are—is the person of sound or unsound mind; if unsound, are there real lucid intervals; is he fit to manage his affairs, to contract a marriage, or to execute a will; is he dangerous to others?

As grounds for restraint, the law recognizes only these conditions—danger to himself, inability to manage his own affairs and property, and danger to the person of others. Before an individual can be placed under restraint in an asylum the certificates of two medical men must be obtained, and the formal order of a relation or friend. The certificates to be valid must be signed by legally qualified medical practitioners having no interest, direct or indirect, in the patient, or in the asylum to which he is to be sent. The medical examiners must pay separate visits, each medical man examining the patient separately. The certificates, which remain valid for seven days only, must bear the exact address of the lunatic, his occupation, and the date of the examination; they must also set forth distinctly the grounds of the opinion they express, under the separate heads of facts observed by the examiner, and facts (to be specified) communicated by others. In the case of pauper lunatics one medical certificate only is required, which is supplemented by an order from a justice of the peace. In urgent cases also one medical certificate suffices for incarceration in an asylum, provided that within three days of the patient's reception two other such certificates are signed by two other medical practitioners, not being connected with the asylum, upon a like examination. The superintendent or proprietor of the asylum must in all cases forward to the commissioners of lunacy a notice of admission within one clear day from the patient's admission. Any infringement of the statutory regulations subjects the person who commits it to a heavy penalty.

## II. INJURIES TO THE PERSON.

1. *Defloration*.—The signs of defloration are obscure and uncertain; and it is rather by the coexistence of several of the usual marks than the existence of any one sign, that any just conclusion can be arrived at.

2. *Rape*.—This crime consists in the carnal knowledge of a woman

forcibly and against her will. The resistance must be to the utmost, else the crime of rape has not been committed in the legal sense of the word. The proofs of rape, accordingly, apart from the consistency of the woman's story, mainly depend on the presence of the signs of defloration, and on marks of injury on the man.

3. *Mutilation*.—This may consist in the cutting or maiming of any member; castration is the most important, and perhaps not rarely effected as a crime. Self-mutilation, giving rise to false accusations, is occasionally resorted to.

4. *Criminal Abortion*.—The crime of abortion consists in unlawfully administering to a woman, or causing to be taken by her (whether she be with child or not), with intent to procure her miscarriage, any poison or noxious thing, or using for the same purpose any instrument or other means whatsoever; also in the use of the same means, with the same intent, by any woman being with child.

5. *Homicide*.—The legal sense of the term homicide excludes such injuries as are the result of either accident or of suicide. It embraces murder or wilful homicide, manslaughter or culpable homicide, casual homicide, and justifiable homicide.

As a preliminary in all cases of homicide, it is the duty of the medical jurist in the first place to ascertain the fact of death, and to distinguish between real and apparent death; and then to determine, if possible, the period at which death took place.

*Infanticide* or child murder is by the British law treated with the same severity as the murder of an adult. Indeed infanticide as a crime distinct from murder has no legal recognition. Practically this severity defeats itself, and offences which are really cases of child murder are often treated simply as cases of concealment of birth. The iniquity of the old law which threw the onus of proof of still-birth on the mother now no longer exists, and the law demands strict proof of live-birth at the hands of the prosecution. Hence the subject involves very nice points of forensic medicine. The child must be proved to have arrived at the period when there was a probability of its living (proof of viability); and as the establishment of respiration is necessary to prove live-birth the evidences of this act must be carefully investigated. The size and position of the lungs, and the state of the vessels concerned in foetal circulation, must be carefully noted. The foetal lungs are dark, dense, and liver-like in appearance and consistence, and sink when immersed in water; whilst the fully respired lungs are rosy, marbled, and soft and crepitant when handled. Minor degrees of respiration are recognized by the appearance of little groups of dilated air-vesicles, and by the fact that, although the lungs as a whole may sink in water, certain portions of them, into which respired air has penetrated, float in water even after subjection to firm pressure in the hand. Care must be taken, nevertheless, to exclude buoyancy of the lung due to putrefaction; in this case the air may be expelled by gentle pressure, and the previously buoyant portion of lung now sinks in water. It is impossible, however, to distinguish certainly between a lung naturally inflated and one artificially insufflated.

It must be borne in mind that, although live-birth cannot be affirmed in the absence of signs of respiration, the presence of these signs is not proof of live-birth in the legal sense of the term. The law demands for live-birth a separate existence of the child after delivery; and breathing may take place whilst the child is still either wholly or partially within the maternal passages, and in some special cases whilst still within the womb itself.

When proofs of respiration—it may be to such an extent as to leave no doubt as to live-birth—have been found, the cause of death is then to be investigated. Wounds, and other forms of injury, must be sought for. There may be signs of strangulation, suffocation, puncture of the fontanelles, and consequent injury to the brain, the administration of a poison, or other means of procuring death. It must be borne in mind that some of these causes may be brought about by omission, or even by accident. Thus strangulation may arise from natural and unrelieved pressure of the navel string on the neck of the child; suffocation from immersion of the face of the child in the maternal discharges, or by pressure of clothes on the mouth. Death may result from hæmorrhage through neglect to tie the navel string, or the infant may perish from exposure to cold.

In the case of exposed infants it is very important to ascertain the real mother. As such exposure usually takes place soon after birth, comparison of the age of the infant with the signs of recent delivery in the suspected mother is the best method of proving the relation.

Ordinary *homicide* may be accomplished by several modes that may sometimes be ascertained by examination of the body. Of one of the most important of these consideration is deferred to the article *Poisons*.

Death by *asphyxia* is a common mode of accomplishing homicide, as by suffocation, drowning, hanging, strangulation, or by exposure to mephitic air. Suicide and accidental death from these causes are still more common. (1) *Drowning* is thought to produce death occasionally by the suddenness of the shock causing suspension of the functions of circulation and respiration—by shock without a struggle. The usual mode of death appears, however,

to be by the circulation of unoxygenated blood through the brain acting as a poison upon that organ; and this is attended with all the phenomena of asphyxia, as in suffocation. The phenomena attending asphyxia are as follows. As soon as the oxygen in the arterial blood, through exclusion of air, sinks below the normal, the respiratory movements grow deeper and at the same time more frequent; both the inspiratory and expiratory phases are exaggerated, the supplementary respiratory muscles are brought into play, and the breathing becomes hurried. As the blood becomes more and more venous, the respiratory movements continue to increase both in force and frequency. Very soon the expiratory movements become more marked than the inspiratory, and every muscle which can in any way assist in expiration is brought into play. The orderly expiratory movements culminate in expiratory convulsions; these violent efforts speedily exhaust the nervous system, and the convulsions suddenly cease and are followed by a period of calm. The calm is one of exhaustion; all expiratory active movements have ceased, and all the muscles of the body are flaccid and quiet. But at long intervals lengthened deep inspiratory movements take place; then these movements become less frequent; the rhythm becomes irregular, so that each breath becomes a more and more prolonged gasp, which becomes at last a convulsive stretching of the whole body; and with extended limbs and a straightened trunk, with the head thrown back, the mouth widely open, the face drawn, and the nostrils dilated, the last breath is taken. The above phenomena are not all observed except in cases of sudden and entire exclusion of air from the lungs. In slow asphyxia, where the supply of air is gradually diminished (e.g., in drowning), the phenomena are fundamentally the same, but with minor differences. The appearances of the body after death from drowning are various. There may be pallor of the countenance, or this may be livid and swollen. The air passages are filled with frothy mucus, and there may be water in the stomach. The ends of the fingers are often excoriated from grasping at objects; and weeds, &c., are sometimes found grasped in the hands. The distinction between murder and suicide by drowning can rarely be made out by examination of the body alone, and is usually decided from collateral circumstances or marks of a struggle. Attention must also be paid to the existence of wounds on the body, marks of strangulation on the neck, and the like.

(2) *Hanging* may result in death from asphyxia, or, as is more particularly the case in judicial hanging, some injury is inflicted on the upper portion of the spinal cord, resulting in instant death. The ordinary appearances of death from asphyxia may be found: dark fluid blood, congestion of the brain, intensely congested lungs, the right cavities of the heart full, and the left comparatively empty of blood, and general engorgement of the viscera. Ecchymosis may be found beneath the site of the cord, or a mere parchmenty appearance. There may even be no mark of the cord visible. The mark, when present, usually follows an oblique course, and is high up the neck. The fact that a body may be suspended after death, and that if this be done speedily whilst the body is still warm there may be a *post-mortem* mark undistinguishable from the mark observed in death from hanging, must not be forgotten.

(3) *Suffocation* may occur from the impaction of any substance in the glottis, or by covering up the mouth and nose. It is frequently of accidental origin, as when substances become accidentally impacted in the throat, and when infants are overlaid. The phenomena are those of pure asphyxia, which have already been detailed. On *post-mortem* examination the surface of the lungs is found covered with minute extravasations of blood, known as punctated ecchymosis.

(4) *Strangulation* may be accomplished by drawing a cord tightly round the neck, or by forcibly compressing the windpipe (throttling). Hence there may be either a circular mark round the neck, not so oblique as after hanging, or the marks of the fingers may be found about the region of the larynx. The cartilaginous structures of the larynx and windpipe may be broken. The mark of the ligature is often low down in the neck. The signs of asphyxia are present in a marked degree. (5) *Mephitism*.—Death from the inhalation of irrespirable gases is a mode of assassination seldom employed, but is frequently resorted to on the Continent by suicides, charcoal fumes being commonly used for the purpose (see Poisons).

6. *Death from Starvation*.—Cases occur in which it is important to distinguish this from other modes of death. In such cases the skin becomes harsh and dry, and may acquire a peculiar odour; the subcutaneous fat disappears; the gums shrink away from the teeth; the tongue and mouth become dark-coloured and dry; the eyes are bloodshot; the intestines become thin and their coats translucent; the gall-bladder is distended. The period of total abstinence from food required to kill an adult is unknown, and greatly depends upon whether there be access to liquid. In some cases persons have been able to subsist on little or no nourishment for long periods, the body being in a state of quasi-hibernation.

7. *Death from Extremes of Temperature*.—(1) Death from cold is not often observed in the British Isles. A portion only of the body, as the extremity of a limb, may perish from extreme cold. After the first sensation of tingling experienced on exposure to severe cold, loss of sensation supervenes, with languor and an irre-

sistible propensity to sleep. The tendency to this forms an extreme danger in such cases. (2) Death from extreme heat usually occurs in the form of burning and scalding, attended with destruction of a large portion of the cutaneous structures. Here the cause of death is obvious. The human body is capable of exposure to very hot air—as is seen in Turkish baths—for a considerable period with impunity. Sun-stroke is a cerebral affection brought on by too great exposure to a hot atmosphere, especially whilst undergoing fatigue.

8. *Death by Lightning*.—Lightning or an artificial electric current may cause instant death. No visible marks of the effects of the electric current may be left, or the body may be singed or discoloured, or the skin may be perforated at one or two spots.

9. *Wounds*.—The examination of wounds, whether fatal or not, often becomes an important branch of forensic medicine. Wounds are usually divided into *contused*, *lacerated*, *incised*, *punctured*, and *gunshot* wounds. For poisoned wounds see Poisons. Each kind of wound requires to be minutely examined and described, as they are in approved works on surgery. The degree of danger from each should be familiar to the medical jurist; and he should recollect that there is no wound which may not become incidentally fatal from improper treatment, peculiarities of constitution, or accidental inoculation with septic material. Punctured wounds or stabs require minute attention; for there have been instances in which death has been produced by an instrument so small as a pin thrust into a vital part. *Wounds of the head* are always dangerous, especially if the blow has been severe. The person so wounded may die without division of the skin, or fracture of the bones, as happens in what is known as *concussion* of the brain. Contusions which do not divide the skin may fracture the skull; or the inner table of the skull may be fractured without the outer being broken or depressed. Even wounds of the scalp may prove fatal, from inflammation extending towards the brain. Punctured wounds of the head are more dangerous than cuts, as more likely to excite fatal inflammation. When the brain and its membranes are injured, all such wounds are generally fatal. Wounds of the face or organs of sense are often dangerous, always disfiguring, and productive of serious inconvenience.

*Wounds of the neck* are always very serious wherever more than the skin is divided. The danger of opening large blood-vessels, or wounding important nerves, is imminent; even the division of a large vein in the neck has proved immediately fatal, from the entrance of air into the vessel, and its speedy conveyance to the heart. A blow on the neck has instantly proved fatal, from injury to an important nerve, generally the pneumogastric or the sympathetic. Dislocations and fractures of the bones of the neck prove instantly fatal. *Wounds of the chest* are always serious when the cavity is penetrated, though persons may recover from wounds of the lungs, and have even survived for some time considerable wounds of the heart. This last is an important fact; because we are not always to consider the spot where the body of a person killed by a wound of the heart, and apparently remaining where he fell, is found as that in which the fatal wound was inflicted. Instances have occurred of persons surviving severe wounds of the heart for several days. Broken ribs are never without danger; and the same may be said of severe contusions of the chest, from the chance of inflammation extending inwards. Wounds penetrating both sides of the chest are generally considered as fatal; but possibly there may be recovery from such. *Wounds of the abdomen*, when they do not completely penetrate, may be considered as simple wounds, unless when inflicted with great force, so as to bruise the contents of the abdominal cavity; in that case they may produce death without breach of surface, from rupture of some viscus, as sometimes happens from blows or kicks upon the belly. Wounds injuring the peritoneum are highly perilous, from the risk of severe inflammation. Wounds of the stomach or intestines, or of the gall-bladder, generally prove mortal, from the effusion of their contents into the peritoneal cavity producing fatal inflammation. Wounds of the liver, spleen, or kidneys are generally soon mortal, from the great vascularity of those organs. Wounds of the extremities, when fatal, may generally be considered so from excessive hæmorrhage, from the consequences of inflammation and gangrene, or from the shock to the system when large portions of the limb are forcibly removed, as in accidents from machinery, and in wounds from firearms.

10. *Poisonous Food*.—Under certain conditions, various articles of diet, especially butcher meat, eggs, milk, butter, cheese, and honey, may become possessed of poisonous properties, and this may arise from a variety of causes besides the introduction of known and specific poisons. Moreover, certain kinds of animal food—fish chiefly—may have definite toxic properties. Food may be more or less poisonous—(1) from unsoundness, either from putridity or decomposition or disease; (2) from the presence of parasites; (3) from mouldiness, or presence of deleterious microscopic fungi; and (4) where the flesh is that of animals which have fed on noxious plants, and under this head may also be classed poisonous honey, which bees have gathered from poisonous plants. (5) It may be of the nature of poisonous fish, using the term fish in the popular sense. (6) Certain fungi or mushrooms are poisonous. Parasitic diseases would, strictly speaking, come under the first head; but the pre-

ventive measures to be adopted in the use of food infested with parasites will alone be treated of in this place.

(1) *Poisonous Vegetables*.—Unsound or even rotten vegetables and fruits may be consumed, and become fertile sources of varied forms of poisoning, especially in hot summers. The symptoms produced by the ingestion of large quantities of unsound fruit or vegetables are of a diarrhoeal character, not often of an alarming severity, except in the cases of the young and feeble. They may, however, sometimes attain a fatal severity. The cause is usually obvious, and the treatment is simple; mild purgatives, as rhubarb or castor oil, with or followed by opiates, to remove peccant matters from the intestines; and stimulants, as ammonia or alcohol, if there be much collapse. Certain fungi or mushrooms are known to be specifically poisonous, such as the *Amanita muscaria*, or fly-fungus, and others. Certain kinds of mushrooms, usually innocuous, are occasionally poisonous or deleterious; and the cause of this is not always clear. Poisonous fungi produce narcotic and irritant symptoms.

(2) *Poisonous, Tainted, or Putrid Meat*.—The obvious characteristics of good sound flesh meat are that its colour is red—neither pale pink nor deep purple; that it is marbled in appearance; firm and elastic to the touch, scarcely moistening the fingers; having a slight and not unpleasant odour; and that when exposed to the air for a day or two it should neither become dry on the surface nor wet and sodden. Sound meat is acid to litmus paper; unsound meat may be neutral or alkaline. Meat may be tainted with physic administered to the animal. It is a common practice, when a fat and valuable animal is unwell, to physic it, and if its recovery be not speedy to slaughter it. The meat of such animals may often be met with in our markets, and may induce illness from the physic with which it is contaminated. The effects of simple putridity are most varied. It is well known that some nations habitually eat putrid meat, and even prefer it to fresh; and the development of rottenness in eggs for the epicure is an art in China. There is no doubt that habit has much to do with the tolerance by the stomach of putrid meat, whether cooked or uncooked. But tainted game, and indeed all kinds of meat in which putrefaction has commenced, may indubitably produce disease. This is chiefly of a diarrhoeal character, preceded by rigors, and attended with collapse and, it may be, convulsions and other signs of a profound affection of the nervous system. The effects of such tainted meat are slight as compared with those which are produced by the sausage-poison, developed by a sort of modified putrefaction in certain German sausages. These sausages, when they become musty and soft in their interior, nauseous in odour and flavour, and strongly acid to test paper, acquire a highly poisonous character, and are frequently fatal in their effects. The symptoms produced by the use of poisonous flesh are gastric pain, vomiting, diarrhoea, depression, coldness of the limbs, and weak irregular action of the heart. Fatal cases end in convulsions and oppressed respiration, death ensuing from the third to the eighth day. The nature of the sausage-poison, which is probably akin to that of putrid and indeed all non-specifically tainted meats, has been a matter of considerable controversy. Some have held that the poisonous action is due to the development of rancid fatty acids; others believe that a so-called catalytic body is produced, capable of setting up by contact a similar catalytic action. Others have regarded the sausage-poison as due to the formation of pyrogenous acids during the drying or smoking of the sausages. The recent discovery by Selmi of a class of poisonous alkaloids or amides, termed *ptomaines*, developed during putrefaction of animal matters, on the one hand, and the discovery by Ballard and Klein, still more recently, that the fatally poisonous properties of hams prepared according to the American method may be due to the presence of a parasitic bacillus, point to one or other of these two latter causes as that of the effects of sausage-poison. Others again have referred the effects to the presence of a microscopic fungus—*Sarcina botulina*.

The poisonous nature of the flesh of animals which have fed on certain plants—for example, hares which have fed on certain species of rhododendron, pheasants on the kalmia shrub, &c.—has been abundantly demonstrated, and need only be referred to here. The honey from bees which have garnered on poisonous plants, as the azalea, may likewise be deleterious; and the fact is of classic interest. The milk even of goats which have browsed on poisonous herbs has also proved poisonous.

(3) *Diseased Meat*.—The poisonous effects of meat affected with certain parasites—trichinae, cysticerci, trematodes, &c., is an undoubted fact. Great quantities of meat pass through our markets which is undoubtedly the flesh of animals affected with disease, such as foot-and-mouth disease, pleuro-pneumonia, pig typhoid, the so-called scarlatina of swine, sheep-pox, &c.; and the question is quite undecided as to whether such flesh produces any injurious effects. To stop the sale of such meat would be to cut off large sources of our meat supplies. The evils attending the use of such diseased meat, when well cooked, have undoubtedly been exaggerated; but, on the other hand, there is enough evidence to show that the use of certain kinds of diseased meat may be followed by serious

results. Thus it is generally admitted that the flesh of animals which have suffered from pleuro-pneumonia and murrain will give rise to boils and carbuncles. Braxy mutton may also produce disease when eaten. Trichinae will produce trichinosis, flukes, the tape-worm, &c. Hams are occasionally fatally poisonous; and this has been traced to the presence of certain low organisms known as *bacilli*.

(4) *Poisonous Fish*.—Fish is sometimes a poisonous article of food. Cases of poisoning by the so-called shell-fish of the British islands are not unfrequently met with. Generally it is the eating of crabs, lobsters, and mussels which produces such results. These are usually of a distressing rather than of a serious character, nettles-rash being a common symptom. Occasionally, however, fatal results have ensued from the use of mussels. In tropical seas poisonous fish are more plentiful—the golden sardine, the bladder fish, the grey snapper, &c.; and, these being eaten by larger fish, as the barracuda, perch, globe-fish, conger eel, &c., the latter may in turn become poisonous.

Good cookery, that is, exposure to a sufficiently high temperature for a sufficiently lengthened time, is undoubtedly the best measure to adopt short of absolute destruction of unsound and diseased meat. So long as meat is high-priced, and the effects of diseased meat so little understood and so undefined, it will be impossible to induce medical officers of health and sanitary inspectors to seize all the diseased and unsound meat which is daily offered for sale. Notwithstanding all that has been said to the contrary, experienced observers are pretty well agreed that thorough exposure of the meat throughout to the temperature at which albumen is coagulated is destructive to the parasites of flesh. Smoking is less effective. Salting is more effective than smoking; but there is some evidence to show that salting may merely hold the life of organisms in suspense without entirely destroying their vitality; and thus in the conversion of salted pork into hams—a process of re-salting and subsequent drying—the specific germ (a bacillus) has been known to be again rendered harmful. It is not known whether efficient cooking entirely removes the deleterious effects of flesh affected with other than parasitic disease, as for example pleuro-pneumonia.

The curative measures for the results of eating poisonous food cannot be specifically described. They are those which must be arrived at on general principles. Symptoms are to be treated, and the powers of the patient sustained until the deleterious matter is removed by the ordinary channels, or the trichinae have become encysted.

#### HISTORY OF FORENSIC MEDICINE.

The true origin of medical jurisprudence is of comparatively recent date, although traces of its principles may be perceived in remote times. Among the ancient Greeks the principles of medical science appear only to have been applied to legislation in certain questions relating to legitimacy. In the writings of Galen we find, however, remarks on the differences between the foetal and the adult lungs; he also treats of the legitimacy of seven months' children, and discusses feigned diseases. Turning to Rome, we find that the laws of the Twelve Tables fix three hundred days as the extreme duration of utero-gestation. It is doubtful whether the Roman law authorized medical inspections of dead bodies. In the code of Justinian we find *De Statu Hominum*; *De Pœnis et Manumissis*; *De Sicariis*; *De Inspiciendo Ventre Custodiendoque Partu*; *De Muliere quæ peperit undecimo mense*; *De Impotentia*; *De Hermaphroditis*,—titles which show obvious traces of a recognized connexion between medicine and law. It was not, however, by the testimony of living medical witnesses that such questions were to be settled, but on the authority of Hippocrates.

Medical jurisprudence, as a science, dates only from the 16th century. In 1507 the bishop of Bamberg introduced a penal code in which the necessity of medical evidence in certain cases was recognized; and in 1532 the emperor Charles V. persuaded the diet of Ratisbon to adopt a uniform code of German penal jurisprudence, in which the civil magistrate was enjoined in all cases of doubt or difficulty to obtain the evidence of medical witnesses,—as in cases of personal injuries, infanticide, pretended pregnancy, simulated diseases, and poisoning. The true dawn of forensic medicine dates, however, from the publication in 1553 of the *Constitutio Criminalis Carolina* in Germany. A few years later Weiher, a physician, having undertaken to prove that witches and demoniacs are, in fact, persons subject to hypochondriasis and hysteria, and should not be punished, aroused popular indignation, and was with difficulty rescued from the flames by his patron, William duke of Cleves.

At the close of the 16th century Ambrose Paré wrote on monsters, on simulated diseases, and on the art of drawing up medico-legal reports; Pineau also published his treatise on virginity and deforation. About the same time as these stimuli to the study of forensic medicine were being made known in Paris, the first systematic treatise on the science appeared in Sicily in the form of a treatise *De Relationibus Medicorum* by Fidele. Paulo Zacchia, the illustrious Roman medical jurist, moreover, published from 1621

to 1635 a work entitled *Quæstiones Medico-Legales*, which marks a new era in the history of the science,—a work which displays an immense amount of learning and sagacity in an age when chemistry was in its infancy, and physiology very imperfectly understood. The discovery of the circulation of the blood by Harvey soon followed, and gave a new impetus to the study of those branches of forensic medicine having direct relations to physiology; and to Harvey we owe the idea how to apply Galen's observations on the differences between the fetal and the adult lungs to the elucidation of cases of supposed infanticide. About this time, too, Sebiz published two treatises, on the signs of virginity and on the examination of wounds respectively. In the former he contended that the hymen was the real mark of virginity; but this was denied by Augenio and Gassendi. In 1663 Bartholin, a Danish physician, investigated the period of human uterine gestation, a subject which had engaged the attention of Aristotle. He also proposed the "hydrostatic test" for the determination of live-birth—a test still in use, and applied by observing whether the lungs of an infant float or sink in water. Swammerdam explained the rationale of the process in 1677; but it was not till 1682 that it was first practically applied by Jan Schreyer.

Germany, ever the leader in questions of forensic medicine, introduced the first public lectures on medical jurisprudence. Michaelis gave the first course about the middle of the 17th century in the university of Leipsic; and these were followed by the lectures of Bohn, who also published *De Renunciatione Vulnerum; cui accesserunt Dissertationes binæ de partu enecato, et an quis vivus mortuusque agnus submersus, strangulatus, aut vulneratus fuerit, et De Officiis Medici Duplicibus, Civici et Forensis*. Welsch and Amman wrote on the fatality of wounds, and Licetus on monsters.

From the time of Ambrose Paré the mode of conducting investigations in forensic medicine had attracted attention in France; and in 1603 Henry IV. authorized his physician to appoint persons skilled in medicine and surgery to make medico-legal inspections and reports in all cities and royal jurisdictions; in 1692, difficulties having arisen, Louis XIV. created hereditary royal physicians and surgeons for the performance of like duties. These, having become a corrupt and venal body, were suppressed in 1790. The only works on forensic medicine which appeared in France during the 17th century, however, were Gendry's *Sur les Moyens de bien rapporter à Justice*, and Bégny's *Doctrines des Rapports en Chirurgie*. At the beginning of the 18th century the latter was superseded as a text-book by Devaux's *L'art de faire des rapports en Chirurgie*. Valentini followed with two works, which were finally incorporated in his *Corpus Juris Medico-Legale* which appeared in 1722. This work is a vast storehouse of medico-legal information, and a summary of the knowledge of the time.

Professorships for teaching the subject were founded in the German universities early in the 18th century, and numerous treatises on forensic medicine were published. Teichmeyer's *Institutiones Medicinæ Legalis* long formed the text-book of the subject; and Alberti, professor of legal medicine at Halle, in his *Systema* gave to the world a most complete and laborious treatise on the science. His industrious collection of facts renders his works a precious mine of information. Indeed towards the close of last century the Germans were almost the only cultivators of legal medicine. But in France the celebrated case of Villeblanche attracted attention to the subject, and called forth Louis, who in a memoir on utero-gestation attacked with powerful arguments the pretended instances of protracted pregnancy, and paved the way for the adoption in the *Code Napoléon* of three hundred days as the limit of utero-gestation, a period in precise accordance with the ancient Roman law of the Twelve Tables. Louis also wrote on death from hanging, and pointed out the mode by which we may distinguish murder from suicide under such circumstances. It is he who is credited with having been the first in France to publicly teach the just application of medical knowledge to jurisprudence. Fodéré's celebrated *Traité de Médecine Légale* appeared in 1798, and marks a new era in the annals of legal medicine.

No British author wrote systematically on forensic medicine till 1788, when Dr Samuel Farr published a short treatise on the *Elements of Medical Jurisprudence*; but this was merely an abridgment of an earlier work of Fazellius. Previous writers, as Mead, Munro, Denman, Percival, and the two Hunters, had, however, dealt with fragments of the subject; nevertheless the science as a whole was little appreciated or recognized in this country during the last century.

In the present century France took the lead; and the institution of three professorships of forensic medicine at the end of the 18th century produced excellent fruits. In 1814 Orfila, a Spaniard by birth, but naturalized in France, published his *Toxicologie*, a work which revolutionized this branch of medical jurisprudence, and first placed the knowledge of poisons upon a scientific basis. Since the time of Orfila, France has never ceased to have one or more living medical jurists, among the most recent of whom we must enumerate Tardien, whose treatises on abortion, on poisons, on wounds,

&c., are justly celebrated. Germany too has industriously pursued the subject, and Casper's great work on forensic medicine will ever remain a classic in the science. In Russia Dragendorff has greatly contributed to our knowledge of poisons.

Though forensic medicine may be said to have been entirely neglected in England till the beginning of the present century, its progress has since been by no means slow or unimportant; and the subject now forms a recognized and obligatory portion of medical study. The first lectures delivered in Great Britain were given in the university of Edinburgh in 1801 by the elder Dr Duncan; and the first professorship was held by his son in 1803. Dr Alfred Swaine Taylor gave the first course of lectures delivered in England, at Guy's Hospital in 1831; and in 1863 the university of London made forensic medicine a separate subject for examination and honours for medical graduates. In 1822 there was not in the English language any treatise of authority either on medical jurisprudence or on any important division of the subject; for it was not till the following year that the useful compendium of Paris and Fonblanque was published; and even half a century ago medical jurisprudence may be said to have been almost in its infancy as compared with what it is now. Since 1829 Great Britain has produced an abundant crop of literature on forensic medicine. Sir Robert Christison's admirable treatise on *Toxicology*, Dr A. S. Taylor's *Principles and Practice of Medical Jurisprudence*, the same author's *Elements of Medical Jurisprudence*, Dr Guy's *Forensic Medicine*, and Ogston's *Lectures on Medical Jurisprudence* are well-known and widely circulated works. The separate memoirs of Taylor, Christison, Guy, and others are also storehouses of facts and deductions in the science.

America, too, has not been behind hand in the race. Wharton and Stillé's *Manual* and Wormley's *Toxicology* are the best-known works of American authors. (T. S. \*)

**MEDICI.** This family is renowned in Italian history for the extraordinary number of statesmen to whom it gave birth, and for its magnificent patronage of letters and art. It emerged from private life and rose to power by means of a very subtle policy that was persistently pursued from generation to generation. The origin of the family is buried in obscurity. Some court historians indeed declare it to have been founded by Perseus, and assert that Benvenuto Cellini's bronze Perseus holding on high the head of Medusa was executed and placed in the Loggia dei Lanzi to symbolize the victory of the Medici over the republic. But this only proves that the real origin of the family is unknown, and equally unknown is the precise signification of the Medicean arms—six red balls on a field of gold.

The name appears in Florentine chronicles as early as the close of the 12th century, although only casually mentioned in connexion with various offices of the republic. The first of the family to be a distinct figure in history was Salvestro dei Medici, who, in the year 1378, took an active part in the revolt of the Ciompi—so-called because it was led by a wool-carder (*ciompo*), one Michele di Lando, and because the chief share in it was taken by the populace, who held the reins of government for some time, and sought to obtain extended political rights. But, although Michele di Lando was the nominal chief of the revolt, Salvestro dei Medici was its real leader. The latter, although a member of the greater guilds, had joined the lesser and sought to be at their head, in order to lay the foundation of his own power and that of his kindred by attacking the Albizzi, who were the leading men of the greater guilds. The victory of the Ciompi, however, was brief, for the excesses of the lower classes brought about a reaction, in which they were crushed, and Michele di Lando sent into banishment. Nevertheless the lesser guilds had gained some ground by this riot, and Salvestro dei Medici the great popularity at which he had aimed. His policy during that period had traced the sole possible road to power in liberty-loving Florence. And this was the road henceforth pursued by the Medici.

On Salvestro's death in 1388 the Albizzi repossessed themselves of the government, and conducted the wars of the republic. Vieri dei Medici, who seems to have been the next head of the family, understanding the temper of

Early bearers of the name. Salvestro.

the times, abstained from becoming a popular leader, and left it to his successors to prosecute the task under easier conditions. Then, in the person of Giovanni, son of Bicci dei Medici (1360-1429), another branch of the family arose, and became from that time forward its representative branch. Indeed this Giovanni may be considered the actual founder of Medicean greatness. He took little part in political affairs, but realized an immense fortune by trade,—establishing banks in Italy and abroad, which in his successors' hands became the most efficient engines of political power. The council of Constance (1414-1418) enabled Giovanni dei Medici to realize enormous profits. Besides, like his ancestor Salvestro, he was a constant supporter of the lesser guilds in Florence. Historians record his frequent resistance to the Albizzi when they sought to oppress the people with heavier taxation, and his endeavours to cause the chief weight to fall upon the richer classes. For this reason he was in favour of the so-called law of *catasto*, which, by assessing the property of every citizen, prevented those in power from arbitrarily imposing taxes that unjustly burdened the people. In this way, and by liberal loans of money to all who were in need of it, he gained a reputation that was practically the foundation-stone of the grand family edifice. Giovanni dei Medici died in 1429 leaving two sons, Cosimo (1389-1464) and Lorenzo (1395-1440). From the former proceeded the branch that held absolute sway for many generations over the nominal republic of Florence, and gave to Italy popes like Leo X. and Clement VII. On the extinction of this elder line in the 16th century, the younger branch derived from Lorenzo, Cosimo's brother, seemed to acquire new life, and for two centuries supplied grand-dukes to Tuscany. Cosimo, surnamed Cosimo the Elder, to distinguish him from the many others bearing the same name, and honoured after his death by the title of *Pater patriæ*, first succeeded in solving the strange problem of becoming absolute ruler of a republic that was keenly jealous of its liberty, without holding any fixed office, without suppressing any previous form of government, and always preserving the appearance and demeanour of a private citizen. Born in 1389, he had already reached the age of forty at the time of his father's death. He had a certain amount of literary culture, and throughout his life showed much taste and an earnest love both for letters and art. But his father had mainly trained him to commerce, for which he had a special liking and aptitude. In fact he was devoted to business to the day of his death, and like his forefathers derived pecuniary advantage from his friendly relations with the papal court. He accompanied Pope John XXIII. to the council of Constance, transacted a vast amount of business in that city, and made very large gains. He then travelled in Germany, and after his return to Florence discharged several ambassadorial missions. At the death of his father he was possessed of a vast fortune and an extended experience, and inherited the leadership of the opposition to the then dominant party of the greater guilds headed by Rinaldo degli Albizzi, Palla Strozzi, and Niccolò da Uzzano. Of gentle and kindly manners, generous in lending and even in giving money whenever he could gain popularity by that means, at critical moments he frequently came to the succour of the Government itself. He was very dexterous in turning his private liberalities to account for the increase of his political prestige, and showed no less acumen and still fewer scruples in making use of his political prestige for purposes of pecuniary profit. Indeed, whenever his own interests were at stake, he showed himself capable of positive villainy, although this was always tempered by calculation. Cosimo proved his skill in these knavish arts during the war between Florence and Lucca. He had joined the Albizzi in urging on this war, and many writers assert

that he turned it to much pecuniary advantage by means of loans to the Government and other banking operations. When, however, military affairs went badly, Cosimo joined the discontented populace in invectives against the war and those who had conducted it. This won him an enormous increase of popularity, but the hatred of the Albizzi and their friends augmented in equal degree, and a conflict became inevitable. The Albizzi, who were far more impetuous and impatient than Cosimo, were now bent upon revenge. In 1433 one of their own friends, Bernardo Guadagni, was elected gonfalonier, and thereupon Cosimo dei Medici was called to the palace and summarily imprisoned in the tower. A general assembly of the people was convoked and a "balia" chosen, which changed the Government and sent Cosimo into exile. Undoubtedly the Albizzi party would have preferred a heavier sentence, but they did not dare to attempt their enemy's life, being well aware of the great number of his adherents. Cosimo had some apprehension that he might be poisoned in prison, but Federigo dei Malavolti, captain of the palace guard, showed him the utmost kindness, and, in order to soothe his fears, voluntarily shared his meals. On the 3d October the prisoner was sent to Padua, his allotted place of exile.

The Albizzi speedily saw that they had done either too much or too little. While seeking to keep the government entirely in their own hands, they beheld the continual growth of the Medici party. When it was necessary to make a campaign in Romagna against the mercenary captains commanding the forces of the duke of Milan, it was plainly seen that in banishing Cosimo the republic had lost the only citizen banker in a position to assist it with considerable loans. The Florentines were defeated by Piccinino in 1434, and this event greatly increased the public exasperation against the Albizzi. Meanwhile Cosimo, who had gone to Padua as a private individual, was entertained there like a prince. Then, being permitted to transfer his residence to Venice, he entered on a course of lavish expenditure. He was overwhelmed with letters and appeals from Florence. Finally, on the 1st of September 1434, a signory was elected composed of his friends, and his recall was decreed. Rinaldo degli Albizzi determined to oppose it by force, and rushed to the Piazza with a band of armed men; but his attempt failed, and he left the country to return no more. The Medici were now reinstated in all their former dignities and honours, and Cosimo, on the evening of September 6th, rode past the deserted mansions of the Albizzi and re-entered his own dwelling after an exile of a year. For three centuries, dating from that moment, the whole history of Florence was connected with that of the house of Medici.

Cosimo's first thought was to secure himself against all future risk of removal from Florence, and accordingly he drove the most powerful citizens into exile to all parts of Italy. Nor did he spare even his former political adversary, Palla Strozzi, although the latter had been favourable to him during the recent changes. His rigour in this particular case was universally censured, but Cosimo would tolerate no rivals in the city, and was resolved to abase the great families and establish his power by the support of the lower classes. He was accustomed to say that states could not be ruled by paternosters. Still, when cruelty seemed requisite, he always contrived that the chief odium of it should fall upon others. When Neri Capponi, the valiant soldier and able diplomatist, gained great public favour by his military prowess, and his influence was further increased by the friendship of Baldaccio d'Anghiari, captain of the infantry, Cosimo resolved to weaken his position by indirect means. Accordingly, when in 1441 a partisan of the Medici was elected gonfalonier, Baldaccio was instantly summoned to the palace, imprisoned,

murdered, and his body hurled from the window. No one could actually fix this crime upon Cosimo, but the majority believed that he had thus contrived to rid himself of one enemy and cripple another without showing his hand. It was impossible for Cosimo openly to assume the position of tyrant of Florence, nor was it worth his while to become gonfalonier, since the term of office only lasted two months. It was necessary to discover some other way without resorting to violence; he accordingly employed what were then designated "civil methods." He managed to attain his object by means of the "balie." These magistracies, which were generally renewed every five years, placed in the ballot bags the names of the candidates from whom the signory and other chief magistrates were to be chosen. As soon as a "balia" favourable to Cosimo was formed, he was assured for five years of having the government in the hands of men devoted to his interests. He had comprehended that the art of politics depended rather upon individuals than institutions, and that he who ruled men could also dictate laws. His foreign policy was no less astute. His great wealth enabled him to supply money not only to private individuals, but even to foreign potentates. Philippe de Comines tells us that Cosimo frequently furnished Edward IV. of England with sums amounting to many hundred thousand florins. When Tommaso Parentucelli was still a cardinal, and in needy circumstances, Cosimo made him considerable loans without demanding guarantees of payment. On the cardinal's accession to the tiara as Nicholas V. he was naturally very well disposed towards Cosimo, and employed the Medici bank in Rome in all the affairs of the curia, which brought immense profits to the house. At the time when Francesco Sforza was striving for the lordship of Milan, Cosimo foresaw his approaching triumph, showed him great friendship, and aided him with large sums of money. Accordingly, when Sforza became lord of Milan, Cosimo's power was doubled. Without the title of prince, this merchant showed royal generosity in his expenditure for the promotion of letters and the fine arts. Numerous edifices were raised and public works accomplished with his purse. Besides his palace in the city, he constructed noble villas at Careggi, Fiesole, and other places. He built the basilica of Fiesole, and that of St Lorenzo in Florence, and enlarged the church and monastery of St Mark. Even in distant Jerusalem he endowed a hospice for the use of pilgrims. The artists of the day comprised men like Donatello, Brunelleschi, Ghiberti, Luca della Robbia, and many others, and Cosimo's magnificent commissions not only developed their powers but stimulated other men of wealth to the patronage of art. Without being a scholar, Cosimo had a genuine taste for letters, and gave them much and efficient patronage. He purchased many Greek and Latin manuscripts; he opened the first public library at St Mark's at his own expense, and founded another in the abbey of Fiesole. The Greek refugees from Constantinople found a constant welcome in his palace. During the council of Florence (1439-1442), Gemisthus Pletho spoke to him with enthusiasm of the Platonic philosophy. Cosimo was so deeply attracted by the theme that he decided to have the young Marsilio Ficino trained in philosophy and Greek learning in order to make a Latin translation of the complete works of Plato. And thus a version was produced that is still considered one of the best extant, and that Platonic academy was founded which led to such important results in the history of Italian philosophy and letters. On the 1st of August 1464 Cosimo breathed his last, at the age of seventy-five, while engaged in listening to one of Plato's dialogues.

The concluding years of his life had been years of little happiness for Florence. Being old and infirm, he had left

the government to the management of his friends, among whom Luca Pitti was one of the more powerful, and they had ruled with disorder, corruption, and cruelty. The lordship of Florence accordingly did not pass without some difficulty and danger into the hands of Piero, surnamed the Gouty, Cosimo's only surviving legitimate son. Afflicted by gout, and so terribly crippled that he was often only able to use his tongue, the new ruler soon discovered that a plot was on foot to overthrow his power. However, showing far more courage than he was supposed to possess, he had himself borne on a litter from his villa to Florence, defeated his enemies' designs, and firmly re-established his authority. But his success may be mainly attributed to the enormous prestige bequeathed by Cosimo to his posterity. Piero died at the end of five years' reign, on the 3d December 1469, leaving two sons, Lorenzo (1449-92) and Giuliano (1453-78). The younger, the gentler and less ambitious of the pair, was, as we shall presently see, quickly removed from the world. Lorenzo, on the contrary, at once seized the reins of state with a firm grasp, and was, chronologically, the second of the great men bestowed upon Italy by the house of Medici. In literary talent he was immensely superior to Cosimo, but greatly his inferior in the conduct of the commercial affairs of the house, for which he had neither aptitude nor inclination. In politics he had nobler conceptions and higher ambitions, but he was more easily carried away by his passions, less prudent in his revenge, and more disposed to tyranny. He had studied letters from his earliest years under the guidance of Ficino and other leading literati of the day, who were constant habitués of the Medici palace. At the age of eighteen he visited the different courts of Italy in order to gain experience of the world and mankind. At his father's death he was only twenty-one years old, but instantly showed his determination to govern Florence with greater despotism than his father or grandfather. He speedily resorted to the system of the "balie," and was very dexterous in causing the first to be chosen to suit his purpose. He then proceeded to humiliate the great families and exalt those of little account, and this was the policy he constantly pursued. His younger brother Giuliano, being of a mild and yielding disposition, had only a nominal share in the government.

Lorenzo's policy was not exempt from danger, but, although prosecuted with less caution, it was still the old astute and fortunate policy initiated by Cosimo. But the grandson bestowed no care upon his commercial interests, although squandering his fortune with far greater lavishness. Accordingly he was sometimes driven to help himself from the public purse without ever being able to assist it as Cosimo had done. All this excited blame and enmity against him, while his greed in the matter of the alum mines of Volterra, and the subsequent sack of that unhappy city, were crimes for which there was no excuse. Among his worst enemies were the Pazzi, and, as they formed a very powerful clan, he sought their ruin by competing with them even in business transactions. They were just on the point of inheriting the large property of Giovanni Borromeo when, in order to prevent this, Lorenzo hurriedly caused a law to be passed that altered the right of succession. The hatred of the Pazzi was thereby exasperated to fury. And in addition to these things there ensued a desperate quarrel with Pope Sixtus IV., a man of very impetuous temper, who, on endeavouring to erect a state on the frontiers of the Florentine republic for the benefit of his nephews, found a determined and successful opponent in Lorenzo. Consequently the Pazzi and Archbishop Salviati, another enemy of Lorenzo, aided by the nephews of the pontiff, who was himself acquainted with the whole matter, determined to put an end to the family.

On the 26th April 1478, while Giuliano and Lorenzo were attending high mass in the cathedral of Florence, the former was mortally stabbed by conspirators, but the latter was able to beat back his assailants and escape into the sacristy. His life saved; and, no longer having to share the government with a brother, Lorenzo profited by the opportunity to wreak cruel vengeance upon his foes. Several of the Pazzi and their followers were hanged from the palace windows; others were hacked to pieces, dragged through the streets, and cast into the Arno, while a great many more were condemned to death or sent into exile. Lorenzo seemed willing and able to become a tyrant. But he stopped short of this point. He knew the temper of the city, and had also to look to fresh dangers threatening him from without. The pope had excommunicated him, put Florence under an interdict, and, being seconded by the Neapolitan king, made furious war against the republic. These hostilities speedily assumed alarming proportions, and the Florentines began to tire of submitting to so many hardships in order to support the yoke of a fellow-citizen. Lorenzo's hold over Florence seemed endangered. But he did not lose heart, and, on the contrary, rose superior to the difficulties by which he was encompassed. He boldly journeyed to Naples, to the court of King Ferdinand of Aragon, who was reputed to be as treacherous as he was cruel, and succeeded in obtaining from him an honourable peace, that soon led to a reconciliation with Sixtus. Thus at last Lorenzo found himself complete master of Florence, and was in a position to turn his power to account. But, as the "balia" changed every five years, it was always requisite, in order to retain his supremacy, that he should be prepared to renew the usual manœuvre at the close of that term and have another elected equally favourable to his aims. This was often a difficult achievement, and Lorenzo showed much dexterity in overcoming all obstacles. In 1480 he compassed the institution of a new council of seventy, which was practically a permanent "balia" with extended powers, inasmuch as it not only elected the chief magistrates, but had also the administration of numerous state affairs. But, this permanent council of his own devoted adherents once formed, his security was firmly established. By this means, the chroniclers tell us, "liberty was buried," but the chief affairs of the state were always conducted by intelligent and experienced men, who promoted the public prosperity. Florence was still called a republic; the old institutions were still preserved, if only in name. Lorenzo was absolute lord of all, and virtually a tyrant. His immorality was scandalous; he kept an army of spies, and frequently meddled in the citizens' most private affairs, and exalted men of the lowest condition to important offices of the state. Yet, as Guicciardini remarks, "if Florence was to have a tyrant, she could never have found a better or more pleasant one." In fact all industry, commerce, and public works made enormous progress. The civil equality of modern states, which was quite unknown to the Middle Ages, was more developed in Florence than in any other city of the world. Even the condition of the peasantry was far more prosperous than elsewhere. And Lorenzo's authority was not confined to Tuscany, but was also very great throughout the whole of Italy. He was on the friendliest terms with Pope Innocent VIII., from whom he obtained the exaltation of his son Giovanni to the cardinalate at the age of fourteen. This boy cardinal was afterwards Pope Leo X. From the moment of the decease of Sixtus IV., the union of Florence and Rome became the basis of Lorenzo's foreign policy. By its means he was able to prevent the hatreds and jealousies of the Sforzas of Milan and the Aragonese of Naples from bursting into the open conflict that long threatened, and after his death actually caused, the beginning of new and irreparable

calamities. Hence Lorenzo was styled the needle of the Italian compass.

But the events we have narrated cannot suffice for the full comprehension of this complex character, unless we add the record of his deeds as a patron of letters and his achievements as a writer. His palace was the school and resort of illustrious men. Within its walls were trained the two young Medici afterwards known to the world as Leo X. and Clement VII. Ficino, Poliziano, Pico della Mirandola, and all members of the Platonic academy were its constant habitués. It was here that Pulci gave readings of his *Morgante*, and Michelangelo essayed the first strokes of his chisel. Lorenzo's intellectual powers were of exceptional strength and versatility. He could speak with equal fluency on painting, sculpture, music, philosophy, and poetry. But his crowning superiority over every other Mæcenas known to history lay in his active participation in the intellectual labours that he promoted. Indeed at certain moments he was positively the leading spirit among the literati of his time. He was an elegant prose writer, and was likewise a poet of real originality. At that period Italians were forsaking erudition in order to forward the revival of the national literature by recurring to the primitive sources of the spoken tongue and popular verse. It is Lorenzo's lasting glory to have been the initiator of this movement. Without being—as some have maintained—a poet of genius, he was certainly a writer of much finish and eloquence, and one of the first to raise popular poetry to the dignity of art. In his *Ambra*, his *Caccia del Falcone*, and his *Nencia da Barberino*, he gives descriptions of nature and of the rural life that he loved, with the graphic power of an acute and tasteful observer, joined to an ease of style that occasionally sins by excess of homeliness. Both in his art and in his politics he leant upon the people. The more oppressive his government, the more did he seek in his verses to incite the public to festivities and lull it to slumber by sensual enjoyments. In his *Ballate*, or songs for dancing, and more especially in his carnival songs, a kind of verse invented by himself, Lorenzo displayed all the best qualities and worst defects of his muse. Marvellously and spontaneously elegant, very truthful and fresh in style, fertile in fancy and rich in colour, they are often of a most revolting indecency. And these compositions of one filling a princely station in the city were often sung by their author in the public streets, in the midst of the populace.

Lorenzo left three sons,—Pietro (1471–1503), Giovanni (1475–1521), and Giuliano (1479–1516). He was succeeded by Pietro, whose rule lasted but for two years. Pietro During this brief term he performed no good deeds, and only displayed inordinate vanity and frivolity. His conduct greatly helped to foment the hatred between Lodovico Sforza and Ferdinand of Naples, which hastened the coming of the French under Charles VIII., and the renewal of foreign invasions. No sooner did the French approach the frontiers of Tuscany than Pietro, crazed with fear, hastened to meet them, and, basely yielding to every demand, accepted terms equally humiliating to himself and the state. But, returning to Florence, he found that the enraged citizens had already decreed his deposition, in order to reconstitute the republic, and was therefore compelled to escape to Venice. His various plots to reinstate himself in Florence were all unsuccessful. At last he went to the south of Italy with the French, was drowned at the passage of the Garigliano in 1503, and was buried in the cloister of Monte Cassino.

The ensuing period was adverse to the Medici, for a republican government was maintained in Florence from 1494 to 1512, and the city remained faithful to its alliance with the French, who were all-powerful in Italy. Cardinal

Cardinal  
Giovanni  
(Leo X.),  
Giuliano,  
Lorenzo.

Giovanni, the head of the family, resided in Rome, playing the patron to a circle of literati, artists, and friends, seeking to increase his popularity, and calmly waiting for better days. The battle of Ravenna wrought the downfall of the fortunes of France in Italy, and led to the rise of those of Spain, whose troops entered Florence to destroy the republic and reinstate the Medici. Pietro had now been dead for some time, leaving a young son, Lorenzo (1492–1519), who was afterwards duke of Urbino. The following year (1513) Cardinal Giovanni was elected pope, and assumed the name of Leo X. He accordingly removed to Rome, leaving his brother Giuliano with his nephew Lorenzo in Florence, and accompanied by his cousin Giulio, who was a natural son of the Giuliano murdered in the conspiracy of the Pazzi, and was soon destined to be a cardinal and ultimately a pope. Meanwhile his kinsmen in Florence continued to govern that city by means of a “*balìa*,” although preserving an empty show of republican institutions. And thus, being masters of the whole of central Italy, the Medici enjoyed great authority throughout the country, and their ambition plumed itself for still higher flights. This was the moment when Niccolò Machiavelli, in his treatise *The Prince*, counselled them to accomplish the unity of Italy by arming the whole country, and expelling its foreign invaders.

Leo X., who is only indirectly connected with the history of Florence, gave his name to the age in which he lived in consequence of his magnificent patronage of art and letters in Rome. But he was merely a clever amateur, and had not the literary gifts of his father Lorenzo. He surrounded himself with versifiers and inferior writers, who enlivened his board and accompanied him wherever he went. He liked to lead a gay and untroubled life, was fond of theatrical performances, satires, and other intellectual diversions. His patronage of the fine arts, his genuine affection for Raphael, and the numerous works he caused to be executed by him and other artists, have served to confer an exaggerated glory on his name. He failed to comprehend the significance of the great religious movement already stirring in Germany, and had not the remotest idea of the grave importance of the Reformation, which indeed he unconsciously promoted by his reckless and shameless sale of indulgences. The whole policy of Pope Leo X. consisted in oscillating between France and Spain, in always playing fast and loose, and deceiving both powers in turn. Yet the evil results of this contemptible policy never seemed to disturb his mind. He finally joined the side of the emperor Charles V., and in 1521, at the time of the defeat of the French by the Spanish troops on the river Adda, he ceased to breathe at his favourite villa of Magliana. Giuliano dei Medici had died during Leo's reign, in 1516, without having ever done anything worthy of record. He was the husband of Philiberta of Savoy, was duke of Nemours, and left a natural son, Ippolito dei Medici (1511–1535), who afterwards became a cardinal. Lorenzo, being of more ambitious temper, was by no means content to remain at the head of the Florence Government hampered by many restrictions imposed by republican institutions, and subject to the incessant control of the pope. In his eagerness to aggrandize his kinsmen, the latter had further decided to give Lorenzo the duchy of Urbino, and formally invested him in its rights, after expelling on false pretences its legitimate lord, Francesco Maria della Rovere. This prince, however, soon returned to Urbino, where he was joyously welcomed by his subjects, and Lorenzo regained possession only by a war of several months, in which he was wounded. In 1519 he also died, worn out by disease and excess. By his marriage with Madeleine de la Tour d'Auvergne, he had one daughter, Caterina dei Medici (1519–89), married in 1533 to Henry, duke of

Orleans, afterwards king of France. She played a long and sinister part in the history of that country. Lorenzo also left a natural son named Alessandro, inheriting the frizzled hair and projecting lips of the negro or mulatto slave who had given him birth. His miserable death will be presently related. Thus the only three surviving representatives of the chief branch of the Medici, Cardinal Giulio, Ippolito, and Alessandro were all of illegitimate birth, and left no legitimate heirs.

Cardinal Giulio, who had laboured successfully for the reinstatement of his family in Florence in 1512, had been long attached to the person of Leo X. as his trusted factotum and companion. He had been generally regarded as the mentor of the pope, who had no liking for hard work. But in fact, his frivolity notwithstanding, Leo X. always followed his own inclinations. He had much aptitude for command, and pursued his shuffling policy without any mental anxiety. Giulio, on the contrary, shrank from all responsibility, muddled his brains in weighing the reasons for and against every possible decision, and was therefore a better tool of government in others' hands than he was fit to govern on his own account. When Giuliano and Lorenzo died, the pope appointed the cardinal to the government of Florence. In that post, restricted within the limits imposed by republican institutions, and acting under the continual direction of Rome, he performed his duties fairly well. He caressed the citizens with hopes of extended liberties, which, although never destined to be fulfilled, long served to keep men's minds in a pleasant flutter of expectation; and when the more impatient spirits attempted to raise a rebellion he speedily quenched it in blood. When, after the death of Leo X. and the very brief pontificate of Adrian VI., he was elected pope (1523) under the name of Clement VII., he entrusted the government of Florence to Cardinal Silvio Passerini conjointly with Alessandro and Ippolito, who were still too young to do much on their own account.

The pontificate of Leo X. had been a time of felicity to himself if of disaster to Italy and the church. The reign of Clement, on the contrary, was fatal to himself as well, a result chiefly due to his hesitating temper and continual uncertainty of mind. His policy, like that of Leo X., consisted in perpetual oscillation between France and Spain. By his endeavours to trick all the world, he frequently ended in being tricked himself. In 1525 he was the ally of the French, who then suffered a terrible defeat at Pavia, where their king Francis I. was taken prisoner. The armies of Charles V. triumphantly advanced, without Clement being able to oppose any effectual resistance. Both Rome and Florence were threatened with a fearful catastrophe.

Thus far we have had no occasion to speak of the younger branch of the Medici, descended from Lorenzo, brother to Cosimo the Elder. Always in obscurity, and always held in check by the elder line, it now seemed to acquire new life, and first entered the arena of history when the other was on the point of extinction. In fact the most valiant captain of the papal forces was Giovanni dei Medici, afterwards known by the name of Giovanni delle Bande Nere. His father was Giovanni, son of Pier Francesco, who was the son of Lorenzo, the brother of Cosimo dei Medici. History has little to tell of the elder Giovanni; but his wife Caterina Sforza, of whom he was the third husband, was a woman of more than masculine vigour. Giovanni dei Medici married her in 1497, but died in 1498, leaving her with one son who was christened Lodovico, but afterwards took his father's name of Giovanni (1498–1526). Trained to arms from his earliest years, this youth inherited all the energy of his mother, whose Sforza blood seemed to infuse new life into the

delle  
Bande  
Nere.

younger branch of the Medici. Notwithstanding his extreme youth, he had already achieved the title of the best captain in Italy. He always fought with immense dash and daring, and was devotedly loved and obeyed by his soldiery. He was the only leader who opposed a determined resistance to the imperial forces. He was seriously wounded at Pavia when fighting on the French side. On his recovery he joined the army of the League, and was much enraged by finding that the duke of Urbino, commander of the Venetian and papal forces, would never decide on attacking. When the imperial troops were struggling through the marshes of Mantua, surrounded on every side, and without stores or ammunition, Giovanni could not resign himself to inactivity like his colleagues in command. He was ignorant that the imperialists had just received supplies and artillery from the duke of Ferrara, and therefore daringly attacked them with a small body of men without taking any precautions for defence. One of the first shots fired by the enemy injured him so fatally that he died a few days after. He was married to Maria Salviati, by whom he had one son, Cosimo (1519-1574), born, as we shall see, to lofty fortunes, for he became the first grand-duke of Tuscany, and indeed the founder of the grand-duchy and the new dynasty.

Meanwhile the imperial army pursued its march upon Rome, captured the Eternal City after a few hours' combat, and cruelly sacked it during many days (1527). Thanks to his perpetual shuffling and excessive avarice, the pope found himself utterly forsaken, and, being unable to defend the city, was obliged to seek refuge in the castle of St Angelo, whence he only effected his escape after some months. He then signed a treaty of alliance with the emperor (1529), who sent an army to besiege Florence and restore the Medici, whom the people had expelled in 1527 on the re-establishment of the republic. After an heroic defence, the city was forced to surrender (1530); and, although it was expressly stipulated that the ancient liberties of Florence should be respected, every one foresaw that the conditions would be violated. In fact, pope and emperor immediately began to dispute as to which should be the new lord of the city. Clement VII. had inherited the traditional family dislike for the younger branch of his kin, and so the choice lay between the two bastards Ippolito and Alessandro. The former being a cardinal, the latter was chosen. Alessandro, who already bore the title of duke of Città di Pienza, came to Florence in 1531, and by imperial patent was nominated head of the republic. According to the terms of this patent, the former liberty enjoyed under the Medicean rule was to remain intact. But no previous ruler of the city had enjoyed hereditary power confirmed by imperial patent, and such power was incompatible with the existence of a republic. Moreover, Clement VII. showed dissatisfaction with the uncertainty of the power conferred upon his kinsman, and finally succeeded in obtaining additional privileges. On the 4th of April 1532 a parliament was convoked for the last time in Florence, and, as usual, approved every measure proposed for acceptance. Accordingly a new council was formed of two hundred citizens elected for life, forty-eight of which number were to constitute a senate. Alessandro, as duke of the republic, filled the post of gonfalonier, and carried on the government with the assistance of three senators, changed every three months, who took the place of the suppressed signory.

The duke's chief advisers, and the contrivers of all these arrangements, were Baccio Valori, Francesco Vettori, and above all Francesco Guicciardini,—men, especially the two latter, of lofty political gifts and extensive influence. The mind and character of Duke Alessandro were as yet comparatively unknown. At first he seemed very anxious

to win the favour of the people, and disposed to rule with justice and prudence. But soon encountering difficulties that he was unable to overcome, he began to neglect the business of the state, treated his new office as affording the means for increased indulgence in pleasure and vice, and acted as if the sole function of government consisted in lulling the people by festivities and corrupting it by the dissolute life of which he set the example. The question of the moment was the transformation of the old republican régime into a principedom; as an unavoidable result of this change it followed that Florence was no longer to be the ruling city to whose inhabitants alone belonged the monopoly of political office. When the leading Florentine families realized, not only that the republic was destroyed, but that they were reduced to equality with those whom they had hitherto regarded as their inferiors and subjects, their rage was indescribable, and hardly a day passed without the departure of influential citizens who were resolved to achieve the overthrow of their new ruler. They found a leader in Cardinal Ippolito dei Medici, who was then in Rome, embittered by the preference given to Alessandro, and anxious to become his successor with the least possible delay. Under the pressure of terror the duke at once became a tyrant. He garrisoned the different cities, and began the erection in Florence of the Fortezza da Basso, built chiefly at the expense of Filippo Strozzi, who afterwards met his death within its walls.

In 1534 Clement VII. died, and the election fell on Paul III., from whom Cardinal Ippolito hoped to obtain assistance for his designs. Accordingly the principal Florentine exiles were despatched on a mission to the emperor Charles V. with complaints of Alessandro's tyranny and his shameless violation of the terms upon which the city had surrendered. Cardinal Ippolito also represented his own willingness to carry on the government of Florence in a more equitable manner, and promised the emperor a large sum of money. Reply being delayed by the emperor's absence, he became so impatient that he set out, accompanied by several exiles, to meet Charles in Tunis, but on the 10th of August 1535 died suddenly by the way, at Itri, poisoned by order of Alessandro. Such at least was the general belief, and it was confirmed by the same fate befalling other enemies of the duke about the same time. On the emperor's return from Africa, the exiles presented themselves to him in Naples, and the venerable patriot Jacopo Nardi pleaded their cause. Duke Alessandro, being cited to appear, came to Naples accompanied by Francesco Guicciardini, who by speaking in his defence rendered himself odious to all friends of liberty, and irretrievably tarnished his illustrious name. The cardinal being dead, it was hard to find a successor to Alessandro. On this account, and perhaps to some extent through the emperor's personal liking for the duke, the latter rose higher than before in the imperial favour, married Margaret of Austria, the natural daughter of Charles, and returned to Florence with increased power. And now Alessandro indulged unchecked in the lowest excesses of tyranny, and although so recently a bridegroom gave way to increased libertinism. His whole time was passed in vicious haunts and in scandalous adventures. In order to conceal the obscurity of his birth, he left his mother to starve, and it was even asserted that he finally got rid of her by poison.

His constant associate in this disgraceful routine was Lorenzo, his distant kinsman Lorenzo, generally known as Lorenzino dei Medici. Of the younger branch of the Medici, the latter was second cousin of the Cosimo already mentioned as the son of Giovanni delle Bande Nere. He had much culture and literary talent, but led an irregular life, sometimes acting like a madman and sometimes like a

villain. He was a writer of considerable elegance, the author of several plays, one of which, the *Aridosto*, was held to be among the best of the age, and he was a worshipper of antiquity. Notwithstanding these tastes, when in Rome he knocked off the heads of some of the finest statues of the age of Adrian, an act by which Clement VII. was so incensed that he threatened to have him hanged. Thereupon Lorenzino fled to Florence, where he became the friend of Duke Alessandro and his partner in the most licentious excesses. They went together to houses of ill-fame, and violated private dwellings and convents. They often showed themselves in public mounted on the same horse. All Florence eyed them with disgust, but no one foresaw the tragedy that was soon to take place.

On the evening of January 5th, 1537, after a day passed in the usual excesses, Lorenzino led the duke to his own lodging, and left him there, promising shortly to return with the wife of Leonardo Ginori. Alessandro, worn out by the exertions of the day, fell asleep on the couch while awaiting Lorenzino's return. Before long the latter came accompanied by a desperado known as the Scoronconcolo, who aided him in falling on the sleeper. Roused by their first thrusts, the duke fought for his life, and was only despatched after a violent struggle. The murderers then lifted the body into bed, hid it beneath the clothes, and, Lorenzino having attached a paper to it bearing the words, *vincit amor patriæ, laudumque immensa cupido*, they both fled to Venice. In that city Lorenzino was assassinated some ten years later, in 1548, at the age of thirty-two, by order of Alessandro's successor. Thus he was only about twenty-two at the time he committed the murder. He wrote an *Apologia*, in which he defended himself with great skill and eloquence, saying that he had been urged to the deed solely by love of liberty. For this reason alone he had followed the example of Brutus and played the part of friend and courtier. The tone of this *Apologia* is so straightforward, sometimes even so eloquent and lofty, that we should be tempted to give it credence were it possible to believe the assertions of one who not only by his crime but by the infamy of his previous and subsequent career completely gave the lie to his vaunted nobility of purpose. By Alessandro's death the elder branch of the Medici became extinct, and thus the appearance of the younger line was heralded by a bloody crime.

When the duke's absence from his own palace was discovered on the morning of January 6th, he was at first supposed to have spent the night with one of his mistresses; but soon, some alarm being felt, search was made, and Cardinal Cybo was the first to discover the murder. Enjoining the strictest secrecy, he kept the corpse concealed for three days, and then had it interred in the sacristy of San Lorenzo. Meanwhile he had hastily summoned Alessandro Vitelli and the other captains, so that, by the time Alessandro's death was made public, the city was already filled with troops. The cardinal then convoked the council of forty-eight to decide upon a successor. Alessandro's only issue was a natural son named Giulio, aged five. The cardinal favoured his election, in the hope of keeping the real sovereignty in his own hands. But he speedily saw the impossibility of carrying out a design that was ridiculed by all. On the other hand, Guicciardini, Vettori, and others of the leading citizens favoured the choice of Cosimo, the son of Giovanni delle Bande Nere. He was already in Florence, was aged seventeen, was keen-witted and aspiring, strong and handsome in person, heir to the enormous wealth of the Medici, and, by the terms of the imperial patent, was Alessandro's lawful successor. Charles V. approved the nomination of Cosimo, who without delay seized the reins of government with a firm grasp. Like Alessandro, he was named head of the

republic; and Guicciardini and others who had worked hardest in his cause hoped to direct him and keep him under their control. But Cosimo soon undeceived them by proving that, his youth notwithstanding, he had a will of his own, and was resolved to rule unshackled by republican forms and unhampered by advisers disposed to act as mentors. The Florentines had now an absolute prince who was likewise a statesman of eminent ability.

On learning the death of Alessandro and the election of Cosimo, the exiles appreciated the necessity for prompt action, as all delay would be fatal to the overthrow of the Medicean rule. They had received money and promises from France; they were strengthened by the adhesion of Filippo Strozzi and Baccio Valori, who had both become hostile to the Medici through the infamous conduct and mad tyranny of Alessandro; and Strozzi brought them the help of his enormous fortune and the prowess of that very distinguished captain, his son Piero. The exiles accordingly met, and assembled their forces at Mirandola. They had about four thousand infantry and three hundred horse; among them were members of all the principal Florentine families; and their leaders were Bernardo Salviati and Piero Strozzi. They marched rapidly, and entered Tuscany towards the end of July 1537. Cosimo on this occasion displayed signal capacity and presence of mind. Fully informed of the exiles' movements by means of his spies, he no sooner learned their approach than he ordered Alessandro Vitelli to collect the best German, Spanish, and Italian infantry at his disposal, and advance against the enemy without delay. On the evening of July 31 Vitelli marched towards Prato with seven hundred picked infantry and a band of one hundred horse, and on the way fell in with other Spanish foot soldiers who joined the expedition. At early dawn the following morning he made a sudden attack on the exiles' advanced guard close to Montemurlo, an old fortress converted into a villa belonging to the Nerli. Having utterly routed them, he proceeded to storm Montemurlo, where Filippo Strozzi and a few of his young comrades had taken refuge and barricaded the gates. Knowing that they must either conquer or die, they made a desperate resistance for some hours, and then, overwhelmed by superior numbers, were obliged to yield themselves prisoners. The main body of the army was still at some distance, having been detained in the mountains by heavy rains and difficult passes, and, on learning the defeat at Montemurlo, its leader refused to advance, and turned back by the way he had come. Alessandro Vitelli then re-entered Florence with his victorious army and his fettered captives. Cosimo had achieved his first triumph.

All the prisoners, who were members of great families, were brought before Cosimo, and were received by him with courteous coldness. Soon, however, a scaffold was erected in the Piazza, and on four mornings in succession four of the prisoners were beheaded. Then the duke saw fit to stay the execution. Baccio Valori, however, and his son and nephew were beheaded on the 20th of August in the courtyard of the Bargello. Filippo Strozzi still survived, confined in the Fortezza da Basso, that had been built at his expense. His family was illustrious, he had numerous adherents, and he enjoyed the protection of the French king. Nevertheless Cosimo only awaited some plausible pretext to rid himself of this dreaded enemy. He brought him to trial and had him put to the question. But this cruelty led to nothing, for Strozzi denied every accusation and bore the torture with much fortitude. On December 18th he was found dead in his prison, with a blood-stained sword by his side, and a slip of paper bearing these words: *eroriare aliquis nostris ex ossibus ultor*. It was believed that, having renounced all hope of his life being spared, Strozzi had preferred suicide to death at the hands of the

Assassi-  
nation of  
Aless-  
andro.

Cosimo I.

executioner. Some, however, thought that Cosimo had caused him to be murdered, and adopted this mode of concealing the crime. The young prince's cold-blooded massacre of his captives cast an enduring shadow upon his reign and dynasty. But it was henceforward plain to all that he was a man of stern resolve, who went straight to his end without scruples or half measures. Before long he was regarded by many as the incarnation of Machiavelli's *Prince*, "inasmuch as he joined daring to talent and prudence, was capable of great cruelty, and yet could practise mercy in due season." Guicciardini, who still pretended to act as mentor, and who on account of his many services had a certain influence over him, was obliged to withdraw from public life and busy himself with writing his *History* at his villa of Arcetri. He died in this retreat in 1540, and it was immediately rumoured that the duke had caused him to be poisoned. This shows the estimation in which Cosimo was now held. It was true that he punished with death all who dared to resist his will. By 1540 sentence of death had been pronounced against four hundred and thirty contumacious fugitives, and during his reign one hundred and forty men and six women actually ascended the scaffold, without counting those who perished in foreign lands by the daggers of his assassins. He reduced the old republican institutions to empty forms, by making the magistrates mere creatures of his will. He issued the sternest edicts against the rebels, particularly by the law known as the "Polverina," from the name of its proposer Jacopo Polverini. This law decreed not only the confiscation of the property of exiles, but likewise that of their heirs, even if personally acquired by the latter. Cosimo ruled like the independent sovereign of a great state, and always showed the capacity, firmness, and courage demanded by that station. Only, his state being small and weak, he was forced to rely chiefly upon his personal talent and wealth. It was necessary for him to make heavy loans to the different European sovereigns, especially to Charles V., the most rapacious of them all, and to give enormous bribes to their ambassadors. Besides, he had to carry on wars for the extension of his dominions, and neither his inherited wealth nor the large sums gained by confiscating the estates of rebellious subjects sufficed for all this outlay. He was accordingly compelled to burden the people with taxes, and thus begin at once to diminish its strength.

Cosimo bore a special grudge against the neighbouring republics of Siena and Lucca. Although the latter was small and weak, and the former garrisoned by Spaniards, yet the spectacle of free institutions at the frontiers of his own state served as a continual incitement to subjects disaffected to the new régime. In fact Francesco Burlamacchi, a zealous Lucchese patriot, had conceived the design of re-establishing republican government in all the cities of Tuscany. Cosimo, with the emperor's help, succeeded in having him put to death. Lucca, however, was an insignificant state making no pretence of rivalry, whereas Siena was an old and formidable foe to Florence, and had always given protection to the Florentine exiles. It was now very reluctantly submitting to the presence of a Spanish garrison, and, being stimulated by promises of prompt and efficacious assistance from France, rose in rebellion and expelled the Spaniards in 1552. Cosimo instantly seized the opportunity, wrote to the emperor in terms that appealed to his pride, asked leave to attack Siena, and begged for troops to ensure the success of his enterprise. As no immediate answer arrived, he feigned to begin negotiations with Henry II. of France, and, by thus arousing the imperial jealousy, obtained a contingent of German and Spanish infantry. Then came a long and bloody war. Siena was besieged for fifteen months, and its inhabitants,

aided by the valour of Piero Strozzi, who fought under the French flag, made a most heroic resistance, even women and children helping on the walls. But fortune was against them. Piero Strozzi sustained several defeats, and finally the Sienese, having exhausted their ammunition and being decimated by famine and the sword, were obliged to capitulate on honourable terms that were shamelessly violated. By the varied disasters of the siege and the number of fugitives the population was reduced from forty to eight thousand inhabitants. The republicans, still eager to resist, withdrew to Montalcino. Cosimo now ruled the city and territory of Siena in the name of Charles V., who always refused him its absolute possession. After the emperor's abdication, and the succession of Philip II. to the Spanish throne, Cosimo at last obtained Siena and Pontorferra by giving up his claim to a sum of 200,000 ducats that he was to have received from Charles V. In 1559 he also captured Montalcino, and thus formed the grand-duchy of Tuscany, but he continued to govern the new state—i.e., Siena and its territories—separately from the old. His rule was intelligent, skilful, and despotic; but his enormous expenses drove him to raise large sums of money by special contrivances unsuited to the country and the people. Hence, notwithstanding the genius of its founder, the grand-duchy held from the first the elements of its future decay. Cosimo preferred to confer office upon men of humble origin in order to have pliable tools, but he also liked to be surrounded by a courtier aristocracy on the Spanish and French pattern. As no Tuscan aristocracy any longer existed, he created new nobles, and tempted foreign ones to come by the concession of various feudal privileges; and, in order to turn this artificial aristocracy to some account, he founded the knightly order of St Stephen, charged with the defence of the coast against pirates, which in course of time won much honour by its prowess. He also established a small standing army for the protection of his frontiers; but, as we have seen, he generally employed German and Spanish troops for his wars, and always had a foreign bodyguard. At the commencement of his reign he opposed the popes in order to maintain the independence of his own state; but later, to obtain help, he truckled to them in many ways, even to the extent of giving up to the Inquisition his own confidant, Piero Carnesecchi, who, being accused of heresy, was beheaded and burnt in 1567. In reward for these acts of submission, the popes showed him friendship, and Pius V. granted him the title of grand-duke, conferring the patent and crown upon him in Rome, although the emperor had always withheld his consent. Finally, however, the latter confirmed the title to Cosimo's successor. The measure most injurious to Tuscany was the fiscal system of taxes, of which the sole aim was to extort the greatest possible amount of money. The consequent damage to industry, commerce, and agriculture was immense, and, added to the devastations caused by the Sienese war, led to their utter ruin. Otherwise Cosimo did not neglect useful measures for the interior prosperity of his state. He was no Mæcenæ, but nevertheless restored the Pisan university, enlarged that of Siena, had the public records classified, and also executed public works like the Santa Trinità bridge. During the great inundations of 1557 he turned his whole energy to the relief of the sufferers.

In 1539 he had espoused Eleonora of Toledo, daughter of the viceroy of Naples, by whom he had several children. Two died in 1562, and their mother soon followed them to the grave. It was said that one of these boys, Don Garcia, had murdered the other, and then been killed by the enraged father. Indeed Cosimo was further accused of having put his own wife to death; but neither rumour had any foundation. He now showed signs of illness and failure

Title of  
grand-duke.

of strength. He was not old, but worn by the cares of state and self-indulgence. Accordingly in 1564 he resigned the government to his eldest son, who was to act as his lieutenant, since he wished to remain the virtual head of the state and have power to resume the sceptre on any emergency. In 1570, by the advice of Pius V., he married Camilla Martelli, a young lady of whom he had been long enamoured. In 1574 he died, at the age of fifty-four years and ten months, after a reign of thirty-seven years, leaving three sons and one daughter besides natural children. These sons were Francesco, his successor, who was already at the head of the government, Cardinal Ferdinand, and Piero.

**Francesco I.** Francesco I., born in 1541, began to govern as his father's lieutenant in 1564, and was married in 1565 to the arch-duchess Giovanna of Austria. On beginning to reign on his own account in 1574, he speedily manifested his real character. His training in the hands of a Spanish mother had made him suspicious, false, and despotic. Holding everyone aloof, he carried on the government with the assistance of a few devoted ministers. He compelled his stepmother to retire to a convent, and kept his brothers at a distance from Florence. He loved the privileges of power without its burdens. Cosimo had known how to maintain his independence, but Francesco cast himself like a vassal at Austria's feet. He reaped his reward by obtaining from Maximilian II. the title of grand-duke, for which Cosimo had never been able to win the imperial sanction, but he forfeited all independence. Towards Philip II. he showed even greater submissiveness, supplying him with large sums of money wrung from his over-taxed people. He held entirely aloof from France, in order not to awake the suspicions of his protectors. In short, under his rule the history of Tuscany was reduced to a mere record of local and municipal events. To increase his funds, he traded on his own account, thus creating a monopoly that was ruinous to the country at large, and led to an enormous number of failures. He raised the tax upon corn to so high a rate that few continued to find any profit in growing it, and thus the Maremme, already partly devastated during the war with Siena, were converted into a desert. Even industry declined under this system of government; and, although Francesco founded porcelain manufactories and pietra dura works, they did not rise to any prosperity until after his death. His love of science and letters was the only Medicean virtue that he possessed. He had an absolute passion for chemistry, and passed much of his time in his laboratory. Sometimes indeed he gave audience to his secretaries of state standing before a furnace, bellows in hand. He took some useful measures to promote the rise of a new city at Leghorn, which at that time had only a natural and ill-sheltered harbour. The improvement of Leghorn had been first projected by Cosimo I., and was carried on by all the succeeding Medici. Francesco was a slave to his passions, and was led by them to scandalous excesses and deeds of bloodshed. His example and neglect of the affairs of the state soon caused a vast increase of crime even among the people, and, during the first eighteen months of his reign, there occurred no less than one hundred and sixty-eight murders.

In default of public events, the historians of this period enlarge upon private incidents, generally of a scandalous or sanguinary kind. In 1575 Orazio Pucci, wishing to avenge his father, whom Cosimo had hanged, determined to get up a conspiracy, but, soon recognizing how firmly the Medicean rule had taken root in the country, desisted from the attempt. But the grand-duke, on hearing of the already abandoned plot, immediately caused Pucci to be hanged from the same window of the Palazzo Vecchio, and even from the same iron stanchion, from which his father before him had hung. His companions, who

had fled to France and England, were pursued and murdered by the ducal emissaries. Their possessions were confiscated, and the "Polverina" law applied so that the conspirators' heirs were reduced to penury, and the grand-duke gained more than 300,000 ducats.

Next year Isabella dei Medici, Francesco's sister, was strangled in her nuptial bed by her husband, Paolo Giordano Orsini, whom she had betrayed. Piero dei Medici, Francesco's brother, murdered his wife Eleonora of Toledo from the same motive. Still louder scandal was caused by the duke's own conduct. He was already a married man, when, passing one day through the Piazza of St Mark in Florence, he saw an exceedingly beautiful woman at the window of a mean dwelling, and at once conceived a passion for her. She was the famous Bianca Cappello, a Venetian of noble birth, who had eloped with a young Florentine named Pietro Buonaventuri, to whom she was married at the time that she attracted the duke's gaze. He made her acquaintance, and, in order to see her frequently, nominated her husband to a post at court. Upon this, Buonaventuri behaved with so much insolence, even to the nobility, that one evening he was found murdered in the street. Thus the grand-duke, who was thought to have sanctioned the crime, was able to indulge his passion unchecked. On the death of the grand-duchess in 1578 he was privately united to Bianca, and afterwards married her publicly. But she had no children, and this served to poison her happiness, since the next in succession was her bitter enemy, the cardinal Ferdinand. The latter came to Florence in 1587, and was ostentatiously welcomed by Bianca, who was most anxious to conciliate him. On October 18th of the same year, the grand-duke died at his villa of Poggio a Caiano, of a fever caught on a shooting excursion in the Maremme, and the next day Bianca also expired, having ruined her health by drugs taken to cure her sterility. But rumour asserted that she had prepared a poisoned tart for the cardinal, and that, when he suspiciously insisted on the grand-duke tasting it first, Bianca desperately swallowed a slice and followed her husband to the tomb.

Such was the life of Francesco dei Medici, and all that can be said in his praise is that he gave liberal encouragement to a few artists, including Giovanni Bologna, who executed for him the group of the Rape of the Sabines. He was the founder of the Uffizi gallery, of the Medici theatre, and the villa of Pratolino; and during his reign the Della Cruscan academy was instituted.

Ferdinand I. was thirty-eight years of age when, in 1587, Ferdinand he succeeded his brother on the throne. A cardinal from the <sup>1</sup> age of fourteen, he had never taken holy orders. He showed much tact and experience in the management of ecclesiastical affairs. He was the founder of the Villa Medici at Rome, and the purchaser of many priceless works of art, such as the Niobe group and many other statues afterwards transported by him to Florence. After his accession he retained the cardinal's purple until the time of his marriage. He was in all respects his brother's opposite. Affable in his manners and generous with his purse, he chose a crest typical of the proposed mildness of his rule,—a swarm of bees with the motto *Majestate tantum*. He instantly pardoned all who had opposed him, and left his kinsmen at liberty to choose their own place of residence. Occasionally, for political reasons, he committed acts unworthy of his character; but he re-established the administration of justice, and sedulously attended to the business of the state and the welfare of his subjects. Accordingly Tuscany revived under his rule and regained the independence and political dignity that his brother had sacrificed to love of ease and personal indulgence. He favoured commerce, and effectually ensured the prosperity of Leghorn, by an edict enjoining toleration towards Jews and

heretics, which led to the settlement of many foreigners in that city. He also improved the harbour and facilitated communication with Pisa by means of the Naviglio, a canal into which a portion of the water of the Arno was turned. He nevertheless retained the reprehensible custom of trading on his own account, keeping banks in many cities of Europe. He successfully accomplished the draining of the Val di Chiana, cultivated the plains of Pisa, Fucecchio, and Val di Nievole, and executed other works of public utility at Siena and Pisa. But his best energies were devoted to the foreign policy by which he sought to emancipate himself from subjection to Spain. On the assassination (1589) of Henry III. of France, Ferdinand supported the claims of the king of Navarre, undeterred by the opposition of Spain and the Catholic League, who were dismayed by the prospect of a Huguenot succeeding to the throne of France. He lent money to Henry IV., and strongly urged his conversion to Catholicism; he helped to persuade the pope to accept Henry's abjuration, and pursued this policy with marvellous persistence until his efforts were crowned with success. Subsequently, however, Henry IV. showed faint gratitude for the benefits conferred upon him, and paid no attention to the expostulations of the grand duke, who then began to slacken his relations with France, and showed that he could guard his independence by other alliances. He gave liberal assistance to Philip III. for the campaign of the latter in Algiers, and to the emperor for the war with the Turks. Hence he was compelled to burden his subjects with enormous taxes, forgetting that while guaranteeing the independence of Tuscany by his loans to foreign powers he was increasingly sapping the strength of future generations. He at last succeeded in obtaining the formal investiture of Siena, which Spain had always considered a fief of her own.

During this grand-duke's reign the Tuscan navy was notably increased, and did itself much honour on the Mediterranean. The war-galleys of the knights of St Stephen were despatched to the coast of Barbary to attack Bona, the headquarters of the corsairs, and they captured the town with much dash and bravery. And in the following year (1608) the same galleys achieved their most brilliant victory in the archipelago over the stronger fleet of the Turks, by taking nine of their vessels, seven hundred prisoners, and a store of jewels of the value of 2,000,000 ducats.

Cosimo  
II.

Ferdinand I. died in 1609, leaving four sons, of whom the eldest, Cosimo II., succeeded to the throne at the age of nineteen. He was at first assisted in the government by his mother and a council of regency. He had a good disposition, and the fortune to reign during a period when Europe was at peace and Tuscany blessed with abundant harvests. Of his rule there is little to relate. His chief care was given to the galleys of St Stephen, and he sent them to assist the Druses against the Porte. On one occasion he was involved in a quarrel with France. Concino Concini, the Marshal d'Ancre, being assassinated in 1617, Louis XIII. claimed the right of transferring the property of the murdered man to De Luynes. Cosimo opposed the decision, and, refusing to recognize the confiscation decreed by the French tribunals, demanded that Concini's son should be allowed to inherit. Hence followed much ill-feeling and mutual reprisals between the two countries, finally brought to an end by the intervention of the duke of Lorraine.

Like his predecessors, Cosimo II. studied to promote the prosperity of Leghorn, and he deserves honour for abandoning all commerce on his own account. But it was no praiseworthy act to pass a law depriving women of almost all rights of inheritance. By this means many daughters of the nobility were driven into convents against their will. He gave scanty attention to the general affairs of the state.

He was fond of luxury, spent freely on public festivities, and detested trouble. Tuscany was apparently tranquil and prosperous; but the decay of which the seeds were sown under Cosimo I. and Ferdinand I. was rapidly spreading, and became before long patent to all and beyond all hope of remedy. The best deed done by Cosimo II. was the protection accorded by him to Galileo Galilei, who had removed to Padua, and there made some of his grandest discoveries. The grand-duke recalled him to Florence in 1610, and nominated him court mathematician and philosopher. Cosimo died in February 1621, after twelve years of a quiet reign marked by no great event. Feeling his end draw near, when he was only aged thirty and all his sons were still in their childhood, he hastened to arrange his family affairs. His mother, Cristina of Lorraine, and his wife, Maddalena of Austria, were nominated regents and guardians to his eldest son Ferdinand II., a boy of ten, and a council of four appointed, whose functions were regulated by law. Accordingly, after Cosimo's death, the young Ferdinand was sent to Rome and Vienna to complete his education, and the government of Tuscany remained in the hands of two jealous and quarrelsome women. Thus the administration of justice and finance speedily went to ruin. Out of submissiveness to the pope, the regents did not dare to maintain their legitimate right to inherit the duchy of Urbino, and in 1623 sanctioned the transfer of that right to the holy see. They conferred exaggerated privileges on the new Tuscan nobility, which became increasingly insolent and worthless. They resumed the practice of trading on their own account, and, without reaping much benefit thereby, did the utmost damage to private enterprise.

In 1627 Ferdinand II., then aged seventeen, returned to Italy and assumed the reins of government; but, being of a very gentle disposition, he decided on sharing his power with the regents and his brothers, and arranged matters in such wise that each was almost independent of the other. He gained the love of his subjects by his great goodness; and, when Florence and Tuscany were cruelly ravaged by the plague in 1630, he showed admirable courage, and carried out many useful measures. But he was totally incapable of energy as a statesman. When the pope made bitter complaints because the board of health had dared to subject certain monks and priests to the necessary quarantine, the grand-duke insisted on his officers asking pardon on their knees for having done their duty. On the death in 1631 of the last duke of Urbino, the pope was allowed to seize the duchy without the slightest opposition on the part of Tuscany. As a natural consequence the pretensions of the Roman curia became increasingly exorbitant; ecclesiastics usurped the functions of the state; and the ancient laws of the republic, together with the regulations decreed by Cosimo I. as a check upon similar abuses, were allowed to become obsolete. On the extinction of the line of the Gonzagas at Mantua in 1627, war broke out between France on the one side and Spain, Germany, and Savoy on the other. The grand-duke, uncertain of his policy, trimmed his sails according to events. Fortunately peace was re-established in 1631. Mantua and Monferrato fell to the duke of Nevers, as France had always desired. But Europe was again in arms for the Thirty Years' War, and Italy was not at peace. Urban VIII. wished to aggrandize his nephews, the Barberini, by wresting Castro and Ronciglione from Odoardo Farnese, duke of Parma and brother-in-law to Ferdinand. Farnese determined to maintain his rights, and marched his army through Tuscany into the territories of the pope, who was greatly alarmed by the attack. Naturally the grand-duke was drawn into the war to defend his own state and his kinsman. His military operations, however, were of the feeblest and often the most laughable character. At

last, by means of the French intervention, peace was made in 1644. But, although the pope was forced to yield, he resigned none of his ecclesiastical pretensions in Tuscany. It was during Ferdinand's reign that the septuagenarian Galileo was obliged to appear before the Inquisition in Rome, which treated him with infamous cruelty. On the death of this great and unfortunate man, the grand-duke wished to erect a monument to him, but was withheld by fear of the opposition of the clergy. The dynasty as well as the country now seemed on the brink of decay. Two of the grand-duke's brothers had already died childless, and Ippolito, the sole survivor, was a cardinal. Accordingly the only remaining heir was Cosimo III., married to a wife who held him in detestation, and did her best to have her marriage annulled or at least obtain a separation.

Like nearly all his predecessors, Ferdinand II. gave liberal patronage to science and letters, greatly aided therein by his brother Leopold, who had been trained by Galileo Galilei, and who joined with men of learning in founding the celebrated academy *Del Cimento*, of which he was named president. This academy took for its motto the words *Provando e riprovando*, and followed the experimental method of Galileo. Formed in 1657, it was dissolved in 1667 in consequence of the jealousies and dissensions of its members, but during its brief existence won renown by the number and importance of its works.

Cosimo  
III.

Cosimo III. succeeded his father in 1670. He was weak, vain, bigoted, and hypocritical. In 1661 he had espoused Louise d'Orléans, niece of Louis XIV., who, being enamoured of Duke Charles of Lorraine, was very reluctant to come to Italy, and speedily detested both her husband and his country, of which she refused to learn the language. She had two sons and one daughter, but after the birth of her third child, Giovan Gastone, her hatred for her husband increased almost to madness. She first withdrew to Poggio a Caiano, and then, being unable to get her marriage annulled, returned to France, where, although supposed to live in conventual seclusion, she passed the greater part of her time as a welcome visitor at court. Even her testamentary dispositions attested the violence of her dislike to her husband.

Cosimo's hypocritical zeal for religion compelled his subjects to multiply services and processions, that greatly infringed upon their working hours. He wasted enormous sums in pensioning converts—even those from other countries—and in giving rich endowments to sanctuaries. Meanwhile funds often failed for the payment of Government clerks and soldiers. His court was composed of bigots and parasites; he ransacked the world for dainties for his table, adorned his palace with costly foreign hangings, had foreign servants, and filled his gardens with exotic plants. He purchased from the emperor the title of "Highness" in order to be the equal of the duke of Savoy. He remained neutral during the Franco-Spanish war, and submitted to every humiliation and requisition exacted by the emperor. He had vague notions of promoting agriculture, but accomplished no results. At one time he caused eight hundred families to be brought over from the Morea for the cultivation of the Maremma, where all of them died of fever. But when, after the revocation of the edict of Nantes, French Huguenots offered to apply their labour and capital to the same purpose, the grand-duke's religious scruples refused them refuge. So ruin fell upon Tuscany. Crime and misery increased, and the poor, who only asked for work, were given alms and sent oftener to church. This period witnessed the rise of many charitable institutions of a religious character under the patronage of the grand duke, as for instance the congregation of San Giovanni Battista. But these could not remedy the general decay.

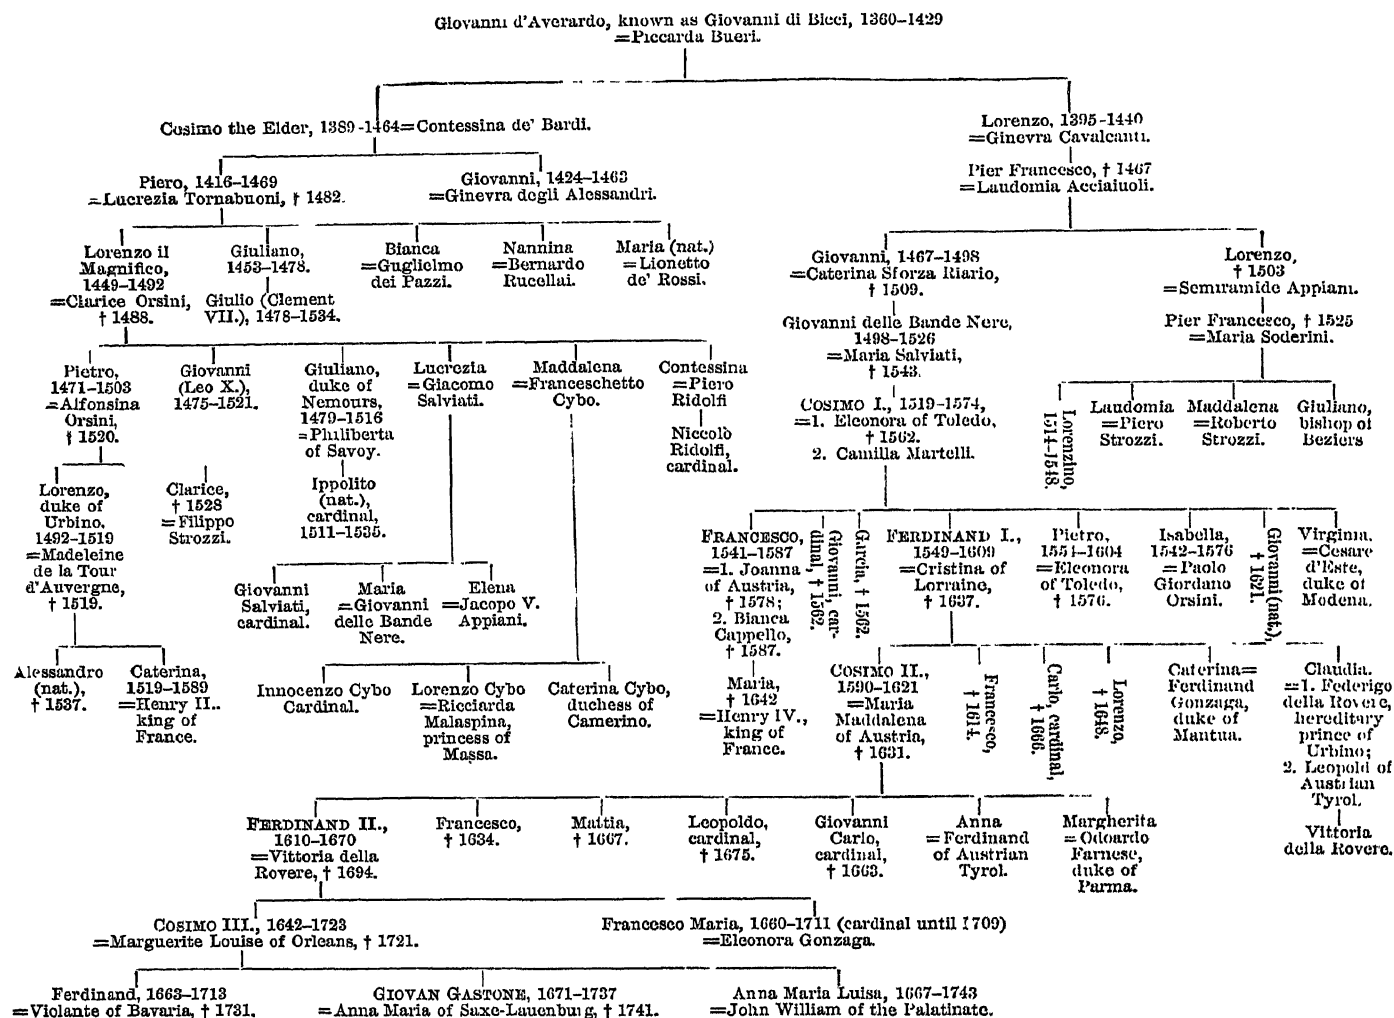

Cosimo's dominant anxiety regarded the succession to

the throne. His eldest son Ferdinand died childless in 1713. The pleasure-loving Giovan Gastone was married to Anna Maria of Saxe-Lauenburg, widow of a German prince, a wealthy coarse woman wholly immersed in domestic occupations, and who seemed little likely to give birth to any children. After living with her for some time in a Bohemian village, Giovan Gastone yielded to his dislike to his wife and her country, withdrew to France, and ruined his health by his excesses. After a brief return to Bohemia he finally separated from his wife, by whom he had no family. Thus the dynasty was doomed to extinction. Cosimo had a passing idea of reconstituting the Florentine republic, but, this design being discountenanced by the European powers, he determined to transfer the succession, after the death of Giovan Gastone, to his sister Anna Maria Louisa, who in fact survived him. For this purpose he proposed to annul the patent of Charles V., but the powers objected to this arrangement also, and by the treaty of 1718 the quadruple alliance of Germany, France, England, and Holland decided that Parma and Tuscany should descend to the Spanish Infante Don Carlos. The grand-duke made energetic but fruitless protests.

Cosimo III. had passed his eightieth year at the time of his decease in October 1723, and was succeeded by his son Giovan Gastone, then aged fifty-three. The new sovereign was in bad health, worn out by dissipation, and had neither ambition nor aptitude for rule. His throne was already at the disposal of foreign powers, and his only thought on ascending it was to regain strength enough to pass the remainder of his days in enjoyment. He dismissed the spies, parasites, and bigots that had formed his father's court, abolished the pensions given to converts, suppressed several taxes, and prohibited the organized espionage established in the family circle. He wished to live and let live, and liked the people to be amused. Everything in fact bore a freer and gayer aspect under his reign, and the Tuscans seemed to feel renewed attachment for the dynasty as the moment of its extinction drew near. But the grand-duke was too feeble and incapable to accomplish any real improvement. Surrounded by gay and dissipated young men, he entrusted all the cares of government to a certain Giuliano Dami, who drove a profitable trade by the sale of offices and privileges. In this way all things were in the hands of corrupt individuals; while the grand-duke, compelled to pass the greater part of his time in bed, vainly sought diversion in the company of buffoons, and was only tormented by perceiving that all the world disposed of his throne without even asking his advice. And when, after prolonged opposition, he had resigned himself to accept Don Carlos as his successor, the latter led a Spanish army to the conquest of Naples, an event afterwards leading to the peace of 1735, by which the Tuscan succession was transferred to Francesco II., duke of Lorraine, and husband of Maria Theresa. Giovan Gastone was finally obliged to submit even to this. Spain withdrew her garrisons from Tuscany, and Austrian soldiers took their place and swore fealty to the grand-duke on the 5th of February 1737. He expired on the 9th July of the same year. Such was the end of the younger branch of the Medici, which had found Tuscany a prosperous country, where art, letters, commerce, industry, and agriculture flourished, and left her poor and decayed in all ways, drained by taxation, and oppressed by laws contrary to every principle of sound economy, downtrodden by the clergy, and burdened by a weak and vicious aristocracy.

## GENEALOGICAL TABLE OF THE MEDICI.

## M E D I C I N E

## PART I.—SYNOPTICAL VIEW OF MEDICINE.

**M**EDICINE, the subject-matter of one of the learned professions, includes, as it now stands, a wide range of scientific knowledge and practical skill. The history of its growth from small beginnings in Greece is traced in the second section of the present article; it remains here to give a synoptical view of medicine, including its scientific or philosophical position, its subdivisions or ramifications as an art and discipline, and its relations to the body politic.

*Scientific Position of Medicine.*—The science of medicine is the theory of diseases and of remedies. While the notion of disease is necessarily or inevitably correlated with the notion of health, there is no necessary and invariable relation, but, on the other hand, a merely conventional association, between a disease and a remedy. That part of the science of medicine which corresponds to the theory of remedies is not therefore in a position scientifically inferior to the theory of diseases; for each article of the *materia medica*—apart from a few inert substances—has a certain effect on the organism in health and in disease, which is ascertainable with scientific precision. Those properties and actions of drugs are the subject of pharmacology and toxicology; the circumstances under which the several articles of the *materia medica* become remedial are the

subject of therapeutics, and therapeutics is dependent for its scientific position upon the completeness of the theory of diseases, or pathology.

Disease is the correlative of health, and the word is not capable of a more penetrating definition. From the time of Galen, however, it has been usual to speak of the life of the body either as proceeding in accordance with nature (*κατὰ φύσιν, secundum naturam*) or as overstepping the bounds of nature (*παρὰ φύσιν, præter naturam*). Taking disease to be a deflexion from the line of health, the first requisite of medicine is an extensive and intimate acquaintance with the norm of the body. The normal condition of the body is capable of being determined without ambiguity; it is the absence from its structures and functions of every disease hitherto known. The structure and functions of the body form the subject of anatomy and physiology.

Physiology is, strictly speaking, the science of that which is *κατὰ φύσιν, or secundum naturam*, and it is usual to say that the theory of diseases is based upon physiology. But, although all that was implied in the Hippocratic term *φύσις (natura)* may be claimed as the subject-matter of physiology, yet, in the ordinary connotation of the term, physiology divides the empire with anatomy. To physiology the functions of the body are usually assigned, and to

anatomy its form and structure. But, as a matter of fact, the structures and functions of the organism are not separable; structure is correlated to function, whether active, dormant, or extinguished, and in like manner function is the twin notion of structure. In the ultimate analysis neither term means anything without the other, and both together mean life. It is owing mostly to its name that physiology is supposed to have a preponderant interest for the theory of disease; the word anatomy is not well adapted to carry its own half of the structure-and-function dualism. Both in the historical development and in the logical connotation, anatomy is as much associated with the living and moving body as physiology itself; but its etymology has always been against it, and it has become more and more difficult to retain for anatomy anything beyond the technicalities of the dissecting-room. The subject of general anatomy has for the most part disappeared from modern text-books, its place being taken by histology, which deals with the minute structure of the simple tissues, and, in a wider acceptance, with the finer anatomy of all the organs and parts of the body. Histology, like anatomy, has had a somewhat technical or descriptive rôle assigned to it; and it is now mainly under physiology that the processes, activities, or living mechanisms of the body fall to be considered. The development of the body as a whole, and of its several tissues and organs, forms the subject of embryology; many of the physiological types of diseased processes, especially the cellular, are discoverable in the embryological period. For the period of development, no arbitrary separation has been attempted hitherto between structure and function, and embryology is, in theory at least, as much physiological as anatomical. The development of function is a legitimate and even desirable subject of scientific study, and a more distinctive place is probably awaiting it in the future; but so indissoluble does the union of structure and function present itself in the period of genesis and growth that the function has hardly as yet come to be abstracted from the structure, or the structure from the function.

The theory of disease rests, therefore, upon physiology, with its more or less technical adjuncts. Pathology is all that physiology is, with the engrossing and difficult element of perturbation, deflexion, or shortcoming added. By virtue of this element of deviation from the line of health, pathology is a discipline apart, with an abundant literature of its own, and with separate academical institutes and chairs. But pathology is also a discipline apart by virtue of concepts proper to itself. A great part of the theory of disease deals with changes or defects of structure and perturbations or failings of function, which may be intricate or difficult to analyse, but are still well within sight of the line of health. Such are the common diseases of the organs and systems—the inflammations, catarrhs, degenerations, hypertrophies, and functional derangements without lesion of the respiratory, circulatory, nervous, genito-urinary, locomotor, and cutaneous systems. Constitutional or general diseases belong also to the province of perturbations from the physiological course,—such diseases as chlorosis, leukæmia, diabetes, gout, rheumatism, scurvy, rickets, Addison's disease, exophthalmic goitre, and the febrile state. Again, congenital deficiencies or malformations, non-cancerous tumours, and the repairing of injuries exemplify no other laws than those of development and growth.

But with those examples the catalogue of physiological diseases is exhausted. We are left with a vast residue of diseases, which have always bulked largely in the popular mind, and have carried the most terrible associations with them. Such are the pestilences or diseases of peoples:—

the plague, sweating sickness, cholera, yellow fever, typhus fever, relapsing fever, typhoid fever, diphtheria, small-pox, measles, scarlet fever, influenza, dengue. Such also are the cancers, consumptions, leprosies, and other loathsome infections. This enormous residue is more than the half of disease, and the definition of disease or the scheme of pathology is brought to a test in finding room within its scientific categories for such maladies as those. The popular imagination in all countries has personified them; medicine in its metaphysical period has regarded them as entities or things in themselves; and it remains to be seen in what way or to what extent medicine in its scientific period will bring them within the category of perturbations of the physiological life.

In considering, for a moment, where to place cancer in the pathological scheme, we shall arrive at a point of view from which the relation of the acute and chronic infections (or contagions) to diseases of the physiological order may be contemplated at least provisionally. Taking cancers, in a generic sense, to mean tumours that have acquired or are possessed of malignancy, we find that such tumours have many points in common with simple tumours,—that they have grown out of the tissues of particular organs or parts under particular (functional) circumstances, and that they may, in general terms, be traced back to that point at which they left the line of health (see PATHOLOGY). The tracing back of tumours along the physiological track is often difficult and laborious; but there is no tumour of the body whose origins are not at length discoverable within the limits of physiological action. That which makes any tumour a cancer is something over and beyond; it is a remarkable acquired property of reproducing its structure in manifold copies, or of infecting the organism of which it is itself a part. The tumour thus becomes a semi-independent power within the body; it may be said, in a political figure, to have acquired *autonomy*, or to have become *imperium in imperio*. A due consideration of such a phenomenon as the infectiveness or cancerousness of some tumours will satisfy one that there are concepts in pathology which carry the investigator entirely beyond physiological bounds or out of sight of the line of health, which bring him face to face with the notion of a disease as a thing in itself, and which thus constitute a peculiar subject-matter. There is nothing that we know among biological phenomena altogether analogous to the semi-independence which an integral part of the body, or condition of the body, manifests towards the organism as a whole, and that, too, strictly in respect of its acquired devious or rebellious habit. The familiar definition of disease, *morbus est vita præter naturam*, which embodies the notion of divergence from the line of health, makes no provision for an acquired autonomy of a morbid state; and that definition has to be supplemented by another, which will recognize the possibility of a disease becoming a thing in itself. The old definition of Van Helmont, *morbus est ens reale subsistens in corpore*, appears to satisfy the requirement; but that definition, although it grew out of the phenomena of disease as observed in fevers, was made too general, and has now associations that are too exclusively ontological and metaphysical. The supplementary definition should be as far as possible in the terms of the principal definition; and we shall provide best in the pathological scheme for such a disease as cancer if, in addition to the formula *morbus est vita præter naturam*, we construct a secondary formula, *morbus est vivum in vivo*.

The notion of autonomy acquired by a morbid state implies, naturally, a pre-autonomous stage of the disease, which had been a mere perturbation of the norm of the body, capable of being measured by the physiological standard. The autonomous stage and the pre-autonomous

stage, which may be demonstrated, in individual cases, for cancers, are a philosophical necessity for all other infective diseases that are marked by morphological features, or by structural characters rooted in and growing out of the proper textures of the body. Thus the peculiar skin eruption of small-pox, which is communicable from person to person, along with a distinctive course of fever, must have had pre-autonomous antecedents (not altogether historically vague) in certain casual conditions of the skin and associated constitutional disturbance, which had recurred and become inveterate, and had so attained to a degree of individuality or a point of autonomy at which they began to be propagated as an organic unit. Again, a second group of infections, exemplified by glanders, bovine tubercle, and syphilis, are rooted in deeper textural processes, which must have been at one time (and may still be) set up by the casual operation of ordinary causes, and at length became the occasion of infective mimicry. It is not so easy to picture (and it is not difficult, with a modern dominant school, to ignore) the casual morbid conditions or ordinary physiological perturbations out of which powerful infections like cholera, typhoid fever, or yellow fever may have arisen; but if the rise and consolidation of their autonomy be a subtle or even untraceable history, yet there are diseases, such as dysentery and erysipelas, which are apt to occur both as casual or spontaneous conditions and as specific infections side by side. Ophthalmia is an example of a purulent catarrh which is constantly arising *de novo* in Egypt from local causes in a non-infective manner, and yet has become, on at least one memorable occasion, a powerful and widespread infection for British troops returning from that country and for the home garrisons for many years subsequently. Infective pneumonia in cattle, and more rarely in man, is an analogous case. In such an episode we observe the actual rise of the disease-autonomy. Again, all the infective diseases have degrees of intensity, at one extreme of which there must occur the vanishing point of their infective property; and those gradations of infectiveness are nowhere more noticeable than in the relation of cholera to choleraic diarrhoea. Further, the remarkable group of climatic fevers are not communicable from person to person (see *MALARIA*); in that respect, and for the reason that the liability of the patient is anything but exhausted by one attack, they are examples of fevers without autonomy. There is not one of the infections that may not be profitably studied from the point of view of its autonomy, and of its more or less obscure pre-autonomous stage. That is a point of view from which even the pestilences and other specific diseases may be regarded as coming within the physiological categories. The large residue of diseases, which are more than perturbations of the physiological life, may still be joined by natural descent to the class of simple perturbations, if we can show for them how their autonomy was acquired, or what was their origin as disease-species.

There is an established place in the history of medicine, and there ought therefore to be room in the definition of disease, for epidemic outbreaks of purely psychical diseased states, such as the dancing madness (*Tanzwuth*), and the boys' crusades; the epidemic diffusion of such morbid states is best approached from the point of view of an acquired autonomy (fixed idea) and an infective mimicry.

The physiological definition of disease, *morbus est vita præter naturam*, affords no place for parasitic diseases. However, the supplementary formula that has been proposed to meet the case of diseases existing autonomously in the body, *morbus est vivum in vivo*, will meet the case of parasitic diseases also. According to many pathologists of the present generation, the whole class of pesti-

lences, fevers, and specific infections generally are caused by certain species of minute parasites invading the body; according to one form of that hypothesis the distinctive characters or specific marks (morphological and other) of those diseases are neither more nor less than the appropriate effects wrought upon the textures and fluids of the body by the respective species of parasites. In this way the great group of infective diseases, which are apt to be the stumbling-block of a scientific definition and logical scheme of disease, are easily disposed of by placing them beside the otherwise insignificant group of parasitic diseases. Whether all or any of those diseases are due in a sense to the invasion of parasites, or wholly caused by parasites, are questions that naturally fall to be settled by a careful sifting of a mass of evidence which has already proved to be peculiarly rich in opportunities for mistake. It may be expected that the facts of infective parasitism and the facts of acquired disease-autonomy will in the end find their place in a common theory of specific diseases, which might be expressed in terms of the physiological formula *morbus est vita præter naturam* with the rider *morbus est vivum in vivo*.

The theory of remedies, which forms the second division of the science of medicine, is chiefly based upon pharmacology or toxicology. If pharmacology be considered as not co-extensive with toxicology, it will be taken to be in great part pharmacographia, or the systematic description of articles of the *materia medica*—their source, preparation, physical properties, and the like. Toxicology is in its general sense the investigation of the physiological action of drugs, a science which is largely dependent upon experiments on the lower animals; in a more technical sense toxicology relates to the effects of poisons and the art of detecting them (see *POISONS*). The physiological action of drugs is the key to their therapeutical action. Therapeutics has been defined as "the discovery of the means by which a system of forces competent to eliminate any given perturbation may be introduced into the economy." The adaptation of remedies to diseases is, however, greatly wanting in precision, and continues to be in large part empirical and traditional. It may be objected to the above definition that all diseases are not reducible to the category of "perturbations," and that there is a certain scientific justification for the doctrine of specifics. Besides the articles of the *materia medica* proper, agencies such as electricity, baths, sea-voyages, and changes of climate generally, enter into the consideration of therapeutics, and two of those form the subject of special departments, viz., electro-therapeutics and hydropathy. Regimen and diet are also important factors in the treatment of disease; according to a contention of Hippocrates, it was in the dietetic needs of mankind that the medical art had its origin.

*Subdivisions of Medicine as an Art and Discipline.*—The medical art (*ars medendi*) breaks away at once from the unity of the theory of disease. While there is but one body of pathological doctrine for either sex, for every period of life, and for every region and part of the organism, the practical art divides itself into departments and sub-departments. The most fundamental division is into internal and external medicine, or into medicine proper and surgery. The treatment of wounds, injuries, and deformities, with operative interference in general, is the special department of surgical practice (the corresponding parts of pathology, including inflammation, repair, and removable tumours, are sometimes grouped together as surgical pathology); and where the work of the profession is highly subdivided, surgery becomes the exclusive province of the surgeon, while internal medicine remains to the physician. A third great department of practice is

formed by obstetric medicine or midwifery, and with obstetrics there is usually associated gynaecology, or the diseases peculiar to women. Diseases of children are the subject of a voluminous separate literature. Dermatology (diseases of the skin) is an important province of practice which, like the diseases of women and children, pertains as much to medicine as to surgery. The greatest of the so-called special departments of practice is ophthalmology (diseases and injuries of the eye). Laryngology is a department that owes its existence mainly to the invention of the laryngoscope, its special province being the treatment of the inflammations (ordinary and specific), tumours, and the like, to which the larynx is liable in common with other parts. Diseases of the ear (otology) form even a more restricted department of practice, owing to the comparative inaccessibility of the chief part of the organ of hearing. The congenital condition of deaf-mutism may or may not be taken as falling within the province of the last-mentioned subdivision. Dentistry or odontology is extremely limited in the range of its subject-matter; but it affords great opportunities for refinements of technical skill, and it is given up to a distinct branch of the profession.

The care of the weak-minded and the insane (psychological medicine) is an integral part of medical practice, inasmuch as it is concerned with diseases of the nervous system and with numerous correlated states of other organs; but it occupies a unique place by reason of the engrossing interest of the subjective phenomena. Habitual drunkenness is also a subject of special treatment.

A state of war, actual or contingent, gives occasion to special developments of medical and surgical practice (military hygiene and military surgery). Wounds caused by projectiles, sabres, &c., are the special subject of naval and military surgery; while under the head of military hygiene we may include the general subject of ambulances, the sanitary arrangements of camps, and the various forms of epidemic camp sickness.

The administration of the civil and criminal law involves frequent relations with medicine, and the professional subjects most likely to arise in that connexion, together with a summary of *causes célèbres*, are formed into the department of medical jurisprudence. It is the practice in Great Britain to call independent medical evidence on both sides of a cause, whether the proceedings be civil or criminal.

The system of life assurance is based upon the co-operation of the medical profession. Heredity, constitution, and diathesis are here the chief subjects of general consideration, while prognosis is the skilled faculty specially called into play.

*Relations of Medicine to the Body Politic.*—The statutes of the United Kingdom which have direct relation to medicine are (1) those relating to the public health; (2) those relating to lunacy (and habitual drunkenness); (3) those relating to the status of the medical profession, to dentists, and to pharmaceutical chemists; (4) those relating to restrictions on the "practice" of anatomy and physiology. There are, besides, several statutes in which medicine is concerned indirectly,—such as the Poor Laws, the Prisons Acts, the Shipping Acts, the Registration of Births and Deaths Act, the Sale of Food and Drugs Act, the Sale of Poisons Act, the Factory and Workshops Act, the Artisans' Dwellings (Metropolitan) Act, the Rivers Pollution Prevention Act, the Contagious Diseases (Animals) Act (1878), and the Public Health (Water) Act.

1. Most of the statutes relating to the public health in England and Wales were consolidated by an Act of 1875, the Acts relating to the metropolis being excepted; there are separate statutes of about the same period for Ireland and Scotland. The system of administration is by local

sanitary authorities, in correspondence with the local government boards in London and Dublin and the board of supervision in Edinburgh. The board in London has a medical department, consisting of a chief medical officer, assistant medical officer, and inspectors, while the Dublin and Edinburgh boards are professionally advised on a somewhat different system. The sanitary authorities throughout the United Kingdom are divided into rural, urban, port, and metropolitan (sanitary and nuisance); they are formed out of pre-existing bodies, either the corporations of cities and towns, the improvement commissioners, or the local authorities. A medical officer of health is attached to most of the several sanitary authorities, or to the combined sanitary authorities of a large district; his duties include making reports on the death-rate and the causes of mortality, the denunciation of nuisances and unwholesome dwellings, workshops, &c., inquiries into the local causes or favouring circumstances of epidemic outbreaks of disease, measures to prevent the spread of contagion (by disinfection, isolation, and otherwise), and other more occasional duties arising under a variety of statutes. Each sanitary authority is required by law to appoint an inspector of nuisances, who practically carries out the instructions of the medical officer when there is one.

The Vaccination Acts (consolidated 1871) are an important part of the public health law of the kingdom; they are administered by the local government board, for the most part through the agency of the medical profession at large, but in some populous parishes also by means of public vaccination stations. Prosecutions under the Acts are instituted by the parochial authorities. The practice formerly (and not unsuccessfully) resorted to of inoculating with the small-pox has been made a criminal offence; but there is still much uncertainty as to the theory of vaccination, and, in particular, as to the relation of vaccinia to variola.

Other statutes which were not consolidated in the Public Health Act of 1875 are the Burials Act, the Contagious Diseases Act, and the Quarantine Act. The first of these is administered by a department of the home office, with a medical inspector. The second (1866 and 1869) relates, under a too general title, to the regulation of prostitution in certain garrison towns, the surgeons under the act being appointed by the board of admiralty or the secretary of state for war, and the administration otherwise carried out by the police.

The quarantine laws stand in the somewhat anomalous position of statutes which it is not thought desirable to repeal, while yet they are stripped bare of all their executive machinery. The Quarantine Act can be set in motion, as occasion arises, by an order of council; not only, however, is there no official medical advice at the disposal of the privy council, upon which action under the act might be taken, but there is not even the framework remaining (except the ghost of a quarantine station on the Motherbank between Portsmouth and the Isle of Wight) of the once considerable quarantine establishment, by which the provisions of the Act might be enforced. On the other hand, port sanitary authorities enjoy certain limited powers under the Public Health Acts of isolating vessels arriving with contagious sickness on board. A quarantine at British ports has not been put in force for many years, opinions being divided as to the abstract efficacy and suitableness of quarantine measures to prevent the importation and diffusion of plague, cholera, or yellow fever (see QUARANTINE).

Numerous instances having occurred of the extensive diffusion of scarlet fever, typhoid fever, and diphtheria by means of milk, the privy council has issued an order, under the Contagious Diseases (Animals) Act of 1878, called the Dairies, Milkshops, and Cowsheds Order, with the object of enforcing extreme cleanliness in the premises and appur-

tenances of the milk trade, and particularly of guarding against the well-known liability of milk to take up effluvia existing or arising near it. The order of council having remained inoperative, it is proposed to deal with the matter by a new Act of Parliament, to be administered by the local government board. While cows' milk has thus been recognized by the sanitary law as a carrier of certain of the human contagia, the milk of diseased cows, and more especially of tuberculous cows, continues to be sold with impunity, the alleged communication of tubercular disease from the cow to man being difficult to prove to the satisfaction of the legislature. The want of constant supervision of the slaughter-houses is thought by many to be a serious defect in the sanitary law of the country; and there is no doubt that much flesh of diseased animals (especially the tuberculous) is sold merely as inferior meat.

*Public Health Law of the United States.*—Questions of public health in the United States come under the common law and the statute law. In the larger part of the Union they are subject to the common law only; in a certain number of the States there is statute law; and there has been since 1879 a national board of health and a quarantine law established by Act of Congress. Generally speaking, the public health procedure of the United States suffers from the want of organization. Decisions at common law relate chiefly to nuisances, and to the recovery of damages for loss caused by the same. The first attempt at statute law was an Act of 1866 creating a metropolitan sanitary district and board of health for the city of New York; in 1869 a board of health was created by the State legislature for Massachusetts; the District of Columbia obtained its board of health in 1870; and other States have followed at intervals, so that there are now at least nineteen State boards of health, New York State and Pennsylvania having health boards only for their respective capitals and other individual towns. Besides the municipal boards in those States, there are very few others for towns in the Union, and still fewer for counties. The powers and activity of the boards of health are very various; the Massachusetts board has powers amounting to that of a court, while the function of several of the State boards is hardly more than advisory. The sanitary statutes made by the State legislatures are in some cases very numerous. Wherever questions of quarantine for yellow fever have arisen, as in Louisiana (New Orleans), Georgia, and Alabama, the State board of health has acquired vigour and has enlisted popular support, in the capitals at least; but in most of the States *laissez faire* is the ordinary feeling towards the board and its operations. The medical profession in each State is the most powerful force, and the State medical society is not unfrequently in a semi-official connexion with the sanitary board; on the other hand, it is alleged that the unfortunate sectarian differences in medicine (represented chiefly by homeopathy) have on several occasions prevented the formation of a State board of health, or have tended to paralyse the action of a board already existing. It is a charge also against boards of health, or at least against those in the great political centres, that their efficiency is apt to be impaired by the introduction of irrelevant political considerations in such matters as the making of appointments. The first step towards a national public health law was gained by the Act (approved 3d March 1879) "to prevent the introduction of infectious or contagious diseases into the United States, and to establish a national board of health." The board consists of seven members appointed by the president and of four officials detached from the public departments of State. Its duties are "to obtain information upon all matters affecting the public health, to advise the several departments of the government, the executives of the several States, and the commissioners of the District of Columbia, on all questions submitted to them, or whenever, in the opinion of the board, such advice may tend to the preservation and improvement of the public health." Quarantine was to be a special object of the board's attention, especially the establishment, if possible, of a federal quarantine system which would preserve the legitimate commercial interests of the several States and their seaports. A quarantine law passed in 1879 provides that all vessels coming from any foreign port where contagious or infectious diseases exist shall obtain a bill of health from the consular officer of the United States at the port of sailing. One of the principal functions of the national board of health hitherto has been to institute scientific inquiries into the nature and causation of diseases of national importance, such as malarial fever. Among the acknowledged desiderata in the national sanitary law of the United States are a uniform carrying out of the practice of vaccination—there is no vaccination law in certain States, and in others it is imperfectly applied—and a uniform system of registration of births and deaths. See Bowditch, *Public Hygiene in America, together with a Digest of American Sanitary Law* (by Pickering), Boston, 1877; Billings, *Introduction to Hygiene and Public Health*, edited by Buck (Eng. ed., London), and in the *Transactions of the*

*Internat. Medical Congress*, London, 1880, vol. iv., sect. "Public Health."

*Public Health Law of other Countries.*—In France there is a council of health for each district, composed of medical practitioners, pharmacists, engineers, and other experts, its function being purely advisory with respect to nuisances, unwholesome dwellings, schools, food, drugs, epidemics, and the like. The executive power rests with the prefect (to be carried out by the police), and is often not put in motion even when advice is tendered. In Paris there are two heads of executive, the prefect of the Seine and the prefect of police. The minister of agriculture and commerce is responsible to the chambers. In Prussia there is a certain amount of bureaucratic care of the public health under the ministry for ecclesiastical, educational, and medical affairs. The minister is advised by a scientific commission (*Wissenschaftliche Deputation für das Medicinalwesen*); and there is a subordinate board for each province, and a medical officer for each district or town (*Kreisphysikus*, or *Stadtphysikus*). Numerous offences against the public health are defined in the code, and penalties fixed (see Eulenberg's work, taken from official sources, *Das Medicinalwesen in Preussen*, Berlin, 1874).

2. The lunacy laws have been fully treated of in a special section of the article *INSANITY (q.v.)*. By an Act of 1879 habitual drunkards have been placed in a position somewhat analogous to that of lunatics, and there are now existing certain licensed asylums for their detention.

3. The Acts relating to the status of the medical profession are known as the Medical Acts. The principal measure, passed in 1858, created a body of twenty-four, called the general council of medical education and registration; by a subsequent Act the council received a charter of incorporation, so that it might draw up, and become the publisher and proprietor of, a list and description of official drugs, which should be called the British Pharmacopœia, and should supersede previous pharmacopœias. The principal duty of the medical council is to keep a register of qualified medical practitioners. The preamble of the Act by which the medical register was created asserts the desirability of those in want of medical aid being able to distinguish qualified from unqualified practitioners; and those whose names are on the register are alone presumably qualified. To be a registered medical practitioner confers a certain positive legal status (right to sue for fees, hold appointments, give certificates, &c.); but there is nothing in the English law to prevent any person whomsoever from practising medicine and taking fees, provided he does not assume misleading titles. Those who are entitled (on payment of five pounds) to have their names inserted in the medical register are graduates in medicine or surgery of the universities of the United Kingdom, licentiates, members, or fellows of the Royal Colleges of Physicians or Surgeons in London, Dublin, and Edinburgh, licentiates or fellows of the Faculty of Physicians and Surgeons of Glasgow, and licentiates of the Apothecaries' Halls of London and Dublin. The council consists of the representatives of those bodies, of six crown nominees, and the president. The medical council possesses certain judicial and executive powers over the names on its register; if, after due inquiry, a registered practitioner be judged by the medical council to have been guilty of infamous conduct in any professional respect, the medical council may, if they see fit, direct their registrar to erase the practitioner's name from the register. The medical council keeps also a register (unpublished) of medical students; whoever has passed a recognized examination in arts, and has forwarded a certificate signed by a teacher of medicine that he has *bona fide* begun the study of medicine, is entitled to have his name entered in the register of students of medicine, with the date of his commencement. The object of the students' register is merely to provide a common and convenient record of the date of commencement of medical study, and, by implication, of the fact that the examination in arts has been passed.

The medical council owes its title of a "council of educa-

tion" to certain powers possessed by it of visiting the examinations of the universities and corporations, and certain ill-defined powers of visiting the medical schools. The council may, if they see fit, report to the privy council any deficiencies that they may have discovered in the teaching or examining, and the privy council may proceed to further steps. But, beyond publishing the reports of their visitations, the medical council do not appear to have had occasion to put the machinery in force. The state has not otherwise interfered to prescribe the subject-matter or the minimum standard of medical education, although there has been at least one unsuccessful attempt by the Government of the day to establish a uniform minimum. By an Act of 1876 parliament has interposed to affirm the principle that women are entitled to become registered practitioners of medicine.

Under the Dentists' Act of 1878 the profession of dentistry acquired a legal status corresponding to that of the medical profession, the general medical council having charge of its register also.

Pharmaceutical chemists are now licensed under an Act passed in 1876; since that date licences are granted only to those who pass either the minor or the major examination of the Pharmaceutical Society of Great Britain, a Pharmacy Act for Ireland (1876) having corresponding provisions.

*The Medical Profession in other Countries.*—In the United States there are usually no restrictions upon the practice of medicine, and in only a few of the States has the medical profession any legal standing. The ordinary medical title is that of doctor of medicine, and that degree is conferred by a large number of institutions after a curriculum of study that varies much in length, and after examinations that are equally various as tests of proficiency. In France the medical profession is divided into two grades: those in the higher grade are all doctors of medicine of the faculties of Paris, Lille, Nancy, Bordeaux, Lyons, or Montpellier; those in the

lower grade are *officiers de santé*. In Germany the right to practise is conferred by a state licence granted on passing the *staats-examen*; the examination, which is almost entirely oral and practical, may be passed in stages at any one of the universities in the empire, the professors of anatomy, physiology, and pathological anatomy being practically *ex officio* examiners, while the other examiners are very frequently also professors in the medical faculty. The *staats-examen* is usually passed before the candidate seeks the degree of doctor of medicine; that degree is almost always taken by those who pass the examination for the state licence, and it is usually conferred after a more or less formal examination of the candidate before the medical faculty, and on the approval of his thesis. In Austria, the right to practise is carried by the degree of doctor of medicine; there is no separate state licence, and no examination except that of the medical faculty of the universities (see Billroth's *Lehren und Lernen der medicinischen Wissenschaften*, Berlin, 1876). In most Continental countries there are penalties directed in effect against practising medicine without the state licence, or the university degree equivalent thereto, and in France the law now extends to resident foreign practitioners who have qualified only in their own country. The regulations for the practice of pharmacy in Germany and other Continental countries have long been of a very stringent kind. The training and licensing of midwives is also under state control.

4. Lastly, the state has interposed to restrict the "practice" of anatomy and physiology. By the Anatomy Act of 1832 (amended in 1871) licences are required for schools of anatomy, as well as licences for teachers, "to practise anatomy." Licensed teachers of anatomy are empowered to receive subjects for dissection under certain conditions. The Act is administered by the home office, with a staff of four inspectors of anatomy, one for the metropolis, one for provincial medical schools in England, and one each for Ireland and Scotland. The Act restricting the practice of physiology is the Vivisection Act of 1876; it is intended for the protection of vertebrate animals liable to be employed alive in physiological experiments, and it resorts to a controlling machinery of licence and inspection similar to that of the Anatomy Act, and under the same Government department. (c. c.)

## PART II.—HISTORY.

The history of medicine falls naturally under two heads, or might be conceivably written from two different points of view. It might be a history of the medical profession or a history of medical doctrine,—in other words, the history of medicine in its relation to society or in its relation to science. We shall here deal chiefly with the history of medical knowledge, remembering also that the histories of anatomy, of physiology, and of surgery are dealt with in the articles referring to those subjects. But a still more trenchant limitation is necessary to preserve the unity of the subject. Attention can be given to so much only of the history as is directly antecedent to and leads up to the medical science of modern Europe. For this purpose, the history of medicine must start with the earlier period of Greek civilization.

*Medicine as Portrayed in the Homeric Poems.*—In the state of society pictured by Homer it is clear that medicine has already had a history. We find a distinct and organized profession; we find a system of treatment, especially in regard to injuries, which it must have been the work of long experience to frame; we meet with a nomenclature of parts of the body substantially the same (according to Daremberg) as that employed long afterwards in the writings of Hippocrates; in short, we find a science and an organization which, however imperfect as compared with those of later times, are yet very far from being in their beginning. The Homeric heroes themselves are represented as having considerable skill in surgery, and as able to attend to ordinary wounds and injuries, but there is also a professional class, represented by Machaon and Podalirius, the two sons of Asclepius, who are treated with great respect. It would appear, too, from the *Æthiopis* of Archinus,

(quoted by Welcker and Haeser) that the duties of these two were not precisely the same. Machaon's task was more especially to heal injuries, while Podalirius had received from his father the gift of "recognizing what was not visible to the eye, and tending what could not be healed." In other words, a rough indication is seen of the separation of medicine and surgery. Asclepius appears in Homer as a Thessalian king, not as a god, though in later times divine honours were paid to him. There is no sign in the Homeric poems of the subordination of medicine to religion which is seen in ancient Egypt and India, nor are priests charged, as they were in those countries, with medical functions,—all circumstances which throw grave doubts on the commonly received opinion that medicine derived its origin in all countries from religious observances.

Although the actual organization of medicine among the Homeric Greeks was thus quite distinct from religion, the worship of Asclepius (or Æsculapius) as the god of healing demands some notice. This cult spread very widely among the Greeks; it had great civil importance, and lasted even into Christian times; but there is no reason to attribute to it any special connexion with the development of the science or profession of medicine. Sick persons repaired, or were conveyed, to the temples of Asclepius in order to be healed, just as in modern times relief is sought by a devotional pilgrimage or from the waters of some sacred spring, and then as now the healing influence was sometimes sought by deputy. The sick person, or his representative, after ablution, prayer, and sacrifice, was made to sleep on the hide of the sacrificed animal, or at the feet of the statue of the god, while sacred rites were performed. In his sleep (*incubatio*, *ἐγκοί-*

ἄριστος) the appropriate remedy was indicated by a dream. Moral or dietetic remedies were more often prescribed than drugs. The record of the cure was inscribed on the columns or walls of the temple; and it has been thought that in this way was introduced the custom of "recording cases," and that the physicians of the Hippocratic school thus learnt to accumulate clinical experience. But the priests of Asclepius were not physicians. Although the latter were often called Asclepiads, this was in the first place to indicate their real or supposed descent from Asclepius, and in the second place as a complimentary title. No medical writing of antiquity speaks of the worship of Asclepius in such a way as to imply any connexion with the ordinary art of healing. The two systems appear to have existed side by side, but to have been distinct, and if they were ever united it must have been before the times of which we have any record. The theory of a development of Greek medicine from the rites of Asclepius, though defended by eminent names, must accordingly be rejected.

*Development of Medicine in Greece.*—It is only from non-medical writers that anything is known of the development of medicine in Greece before the age of Hippocrates. The elaborate collections made by Daremberg of medical notices in the poets and historians illustrate the relations of the profession to society, but do little to prepare us for the Hippocratic period. Nor is much importance to be attached to the influence of the philosophical sects on medicine except as regards the school of Pythagoras. That philosopher and several of his successors were physicians, but we do not know in what relation they stood to later medical schools. We must therefore hasten onward to the age of Pericles, in which Hippocrates, already called "the Great," was in medicine as complete a representative of the highest efforts of the Greek intellect as were his contemporaries the great philosophers, orators, and tragedians. The medical art as we now practise it, the character of the physician as we now understand it, both date for us from Hippocrates. The justification of this statement is found in the literary collection of writings known by his name. Of these certainly many are falsely ascribed to the historical Hippocrates of Cos; others are almost as certainly rightly so ascribed; others again are clearly works of his school, whether from his hand or not. But which are to be regarded as the "genuine works" is still uncertain, and authorities are conflicting. There are clearly two schools represented in the collection,—that of Cnidus in a small proportion, and that of Cos in far the larger number of the works. The latter was that to which Hippocrates belonged, and where he gave instruction; and accordingly it may be taken that works of this school, when not obviously of a different date, are Hippocratic in doctrine if not in actual authorship.

*Hippocratic Medicine.*—The first grand characteristic of Hippocratic medicine is the high conception of the duties and status of the physician, shown in the celebrated "Oath of Hippocrates" and elsewhere,—equally free from the mysticism of a priesthood and the vulgar pretensions of a mercenary craft. So matured a professional sentiment may perhaps have been more the growth of time and organization than the work of an individual genius, but certainly corresponds with the character universally attributed to Hippocrates himself. The second great quality is the singular artistic skill and balance with which the Hippocratic physician used such materials and tools as he possessed. Here we recognize the true Greek *σωφροσύνη*. But this artistic completeness was closely connected with the third cardinal virtue of Hippocratic medicine,—the clear recognition of disease as being equally with life a process governed by what we should now call natural laws, which could be known by observation, and which indicated the

spontaneous and normal direction of recovery, by following which alone could the physician succeed. In the fourth place, these views of the "natural history of disease" (in modern language) led to habits of minute observation and accurate interpretation of symptoms, in which the Hippocratic school was unrivalled in antiquity, and has been the model for all succeeding ages, so that even in these days, with our enormous advances in knowledge, the true method of clinical medicine may be said to be the method of Hippocrates.

The actual science of the Hippocratic school was of course very limited. In anatomy and physiology little advance had been made, and so of pathology in the sense of an explanation of morbid processes or knowledge of diseased structures there could be very little. The most valuable intellectual possession was a large mass of recorded observations in individual cases and epidemics of disease. Whether these observations were systematic or individual, and how they were recorded, are points of which we are quite ignorant, as the theory that the votive tablets in the temples supplied such materials must be abandoned.

Though the Hippocratic medicine was so largely founded on observation, it would be an error to suppose that dogma or theory had no place. The dominating theory of disease was the *humoral*, which has never since ceased to influence medical thought and practice. According to this celebrated theory, the body contains four humours,—blood, phlegm, yellow bile, and black bile, a right proportion and mixture of which constitute health; improper proportions or irregular distribution, disease. It is doubtful whether the treatise in which this theory is fully expounded (*περὶ φύσιος ἀνθρώπου*) is as old as Hippocrates himself; but it was regarded as a Hippocratic doctrine, and, when taken up and expanded by Galen, its terms not only became the common property of the profession, but passed into general literature and common language. Another Hippocratic doctrine, the influence of which is not even yet exhausted, is that of the healing power of nature. Not that Hippocrates taught, as he was afterwards reproached with teaching, that nature is sufficient for the cure of diseases; for he held strongly the efficacy of art. But he recognized, at least in acute diseases, a natural process which the humours went through,—being first of all *crude*, then passing through *coction* or digestion, and finally being expelled by resolution or *crisis* through one of the natural channels of the body. The duty of the physician was to foresee these changes, "to assist or not to hinder them," so that "the sick man might conquer the disease with the help of the physician." The times at which crises were to be expected were naturally looked for with anxiety; and it was a cardinal point in the Hippocratic system to foretell them with precision. Hippocrates, influenced as is thought by the Pythagorean doctrines of number, taught that they were to be expected on days fixed by certain numerical rules, in some cases on odd, in others on even numbers,—the celebrated doctrine of "critical days." This false precision can have had no practical value, but may have enforced habits of minute observation. It follows from what has been said that *prognosis*, or the art of foretelling the course and event of the disease, was a strong point with the Hippocratic physicians. In this they have perhaps never been excelled. Diagnosis, or recognition of the disease, must have been necessarily imperfect, when no scientific nosology, or system of disease, existed, and the knowledge of anatomy was quite inadequate to allow of a precise determination of the seat of disease; but symptoms were no doubt observed and interpreted skilfully. The pulse is not spoken of in any of the works now attributed to Hippocrates himself, though it is mentioned in other works of the collection.

In the treatment of disease, the Hippocratic school attached great importance to diet, the variations necessary in different diseases being minutely defined. Medicines were regarded as of secondary importance, but not neglected, two hundred and sixty-five drugs being mentioned at different places in the Hippocratic works. Blood-letting was known, but not greatly practised. The highest importance was attached to applying all remedies at the right moment, and the general principle enforced of making all influences—internal and external—co-operate for the relief of the patient. The principles of treatment just mentioned apply more especially to the cure of acute diseases; but they are the most salient characteristics of the Hippocratic school. In chronic cases diet, exercise, and natural methods were chiefly relied upon.

The school of Cnidus, as distinguished from that of Cos, of which Hippocrates is the representative, appears to have differed in attaching more importance to the differences of special diseases, and to have made more use of drugs. A treatise on the diseases of women, contained in the Hippocratic collection, and of remarkable practical value, is attributed to this school.

The above sketch of Hippocratic medicine will make it less necessary to dwell upon the details relating to subsequent medical schools or sects in ancient times. The general conception of the physician's aim and task remained the same, though, as knowledge increased, there was much divergence both in theory and practice,—even opposing schools were found to be developing some part of the Hippocratic system. Direct opponents or repudiators of the authority of Hippocrates were rare, all generally appealing to his authority. But, insensibly, the least valuable part of the Hippocratic work, the theory, was made permanent; the most valuable, the practical, neglected.

*Post-Hippocratic Medicine.*—After Hippocrates the progress of medicine in Greece does not call for any special remark in such a sketch as this, but mention must be made of one great name. Though none of Aristotle's writings are strictly medical, he has by his researches in anatomy and physiology contributed greatly to the progress of medicine. It should also be remembered that he was of an Asclepiad family, and received that partly medical education which was traditional in such families, and also himself is said to have practised medicine as an amateur. Moreover, his works on natural history doubtless furthered the progress among the Greeks of sciences tributary to medicine, though the only specimens of such works which have come down to us from the Peripatetic school are those of Theophrastus, who may be considered the founder of the scientific study of botany. Among his encyclopædic writings were some on medical subjects, of which fragments only have been preserved. The Peripatetic school may have been more favourable to the development of medicine, as of other departments of natural knowledge, than any other; but there is no evidence that any of the philosophical schools had important influence on the progress of medicine. The fruit of Aristotle's teaching and example was seen later on in the schools of Alexandria.

The century after the death of Hippocrates is a time almost blank in medical annals. It is probable that the science, like others, shared in the general intellectual decline of Greece after the Macedonian supremacy; but the works of physicians of the period are almost entirely lost, and were so even in the time of Galen. Galen classes them all as of the dogmatic school; but, whatever may have been their characteristics, they are of no importance in the history of the science.

*Alexandrian School of Medicine.*—The dispersion of Greek science and intellectual activity through the world by the conquests of Alexander and his successors led to

the formation of more than one learned centre, in which medicine among other sciences was represented. Pergamum was early distinguished for its medical school; but in this as in other respects its reputation was ultimately effaced by the more brilliant fame of Alexandria. It is here that the real continuation and development of Hippocratic medicine can be traced.

In one department the Alexandrian school rapidly surpassed its Greek original, namely, in the study of anatomy. The dissection of the human body, of which some doubtful traces or hints only are found in Greek times, was assiduously carried out, being favoured or even suggested perhaps by the Egyptian custom of disembowelling and embalming the bodies of the dead. There is no doubt that the organs were also examined by opening the bodies of living persons,—criminals condemned to death being given over to the anatomists for this purpose.

Two eminent names stand in the first rank as leaders of the two earliest schools of medicine which arose in Alexandria, Herophilus and Erasistratus.

Herophilus was a Greek of Chalcidon, a pupil of the schools both of Cos and of Cnidus. He was especially noted for his profound researches in anatomy (see vol. i. p. 802), and in the knowledge and practice of medicine he appears to have been equally renowned. He professed himself a close adherent of Hippocrates, and adopted his theory of the humours. He also made extensive use of drugs, and of bleeding. The reputation of Herophilus is attested by the fact that four considerable physicians wrote works about him and his writings, and he is further spoken of with the highest respect by Galen and Celsus. By the general voice of the medical world of antiquity he was placed only second to Hippocrates.

Erasistratus was the contemporary and rival of Herophilus. Little is known of his life, except that he spent some time at the court of Seleucus Nicator at Antioch before coming to Alexandria, and that he cultivated anatomy late in life, after he had taken up his abode in the latter city. His numerous works are also almost entirely lost, fragments only being preserved by Galen and others. Erasistratus, instead of following Hippocrates as Herophilus did, depreciated him, and seems to have been rather aggressive and independent in his views. He appears to have leaned to mechanical explanations of the symptoms of disease, as was especially the case with inflammation, of which he gave the first rational, though necessarily inadequate, theory.

The two schools composed of the followers of Herophilus and Erasistratus respectively long divided between them the medical world of Alexandria. The names of many prominent members of both sects have been preserved, but it would be useless to repeat them. The Herophilists still revered the memory of Hippocrates, and wrote numerous commentaries on his works. They produced many eminent anatomists, but in the end seem to have become lost in theoretical subtleties, and to have maintained too high a standard of literary cultivation. The school of Erasistratus was less distinguished in anatomy than that of Herophilus, but paid more attention to the special symptoms of diseases, and employed a great variety of drugs. It was longer-lived than that of Herophilus, for it still numbered many adherents in the 2d century after Christ, a century after the latter had become extinct.

The Erasistrateans paved the way for what was in some respects the most important school which Alexandria produced, that known as the empiric, which, though it recognized no master by name, may be considered to have been founded by Philinus of Cos. (280 B.C.), a pupil of Herophilus; but Serapion, a great name in antiquity, and Glaucias of Tarentum, who traced the empirical doctrine

back to the writings of Hippocrates, are also named among its founders. The most striking peculiarity of the empirics was that they rejected anatomy, regarding it as useless to inquire into the causes of things, and thus, as they contended, being the more minute in their observation of the actual phenomena of disease. They professed that their whole practice was based upon experience, to which word they gave a special meaning. Three sources, and three only, could experience draw from:—observation, history (*i.e.*, recorded observation), and judgment by analogy. These three bases of knowledge were known as the “tripod” of the empirics. It should not, however, be forgotten that the empirics read and industriously commented on the works of Hippocrates. They were extremely successful in practical matters, especially in surgery and in the use of drugs, and a large part of the routine knowledge of diseases and remedies which became traditional in the times of the Roman empire is believed to have been derived from them. In the 2d century the school became closely connected with the philosophical sect of the Sceptics, whose leader, Sextus, was an empirical physician. It lived and flourished far beyond this time, when transplanted to Rome, not less than in its native Alexandria, and appears to be recognizable even up to the beginning of the Middle Ages.

If we look at the work of the Alexandrian schools in medicine as a whole, we must admit that the progress made was great and permanent. The greatest service rendered to medicine was undoubtedly the systematic study of anatomy. It is clear that the knowledge of function (physiology) did not by any means keep pace with the knowledge of structure, and this was probably the reason why the important sect of the empirics were able entirely to dispense with anatomical knowledge. The doctrines of Hippocrates, though lightly thought of by the Erasistrateans, still were no doubt very widely accepted, but the practice of the Hippocratic school had been greatly improved in almost every department,—surgery and obstetrics being probably those in which the Alexandrian practitioners could compare most favourably with those of modern times. We have now to trace the fortunes of this body of medical doctrine and practice when transplanted to Rome, and ultimately to the whole Roman world.

*Roman Medicine.*—The Romans cannot be said to have at any time originated or possessed an independent school of medicine. They had from early times a very complicated system of superstitious medicine, or religion, related to disease and the cure of disease, borrowed, as is thought, from the Etruscans; and, though the saying of Pliny that the Roman people got on for six hundred years without doctors was doubtless an exaggeration, and not, literally speaking, exact, it must be accepted for the broad truth which it contains. When a medical profession appears, it is, so far as we are able to trace it, as an importation from Greece.

The first Greek physician whose name is preserved as having migrated to Rome was Archagathus, who came over from the Peloponnesus in 218 B.C.; but there were probably others before him. When Greece was made a Roman province, the number of such physicians who sought their fortunes in Rome must have been very large. The bitter words of M. Porcius Cato, who disliked them as he did other representatives of Greek culture, are evidence of this. The most eminent of these earlier Greek physicians at Rome was Asclepiades, the friend of Cicero (born 124 B.C. at Prusa in Bithynia). He came to Rome as a young man, and soon became distinguished both for his medical skill and his oratorical power. He introduced a system which, so far as we know, was his own, though founded upon the Epicurean philosophical creed; on the

practical side it conformed pretty closely to the Stoic rule of life, thus adapting itself to the leanings of the better stamp of Romans in the later times of the republic. According to Asclepiades all diseases depended upon alterations in the size, number, arrangement, or movement of the “atoms,” of which, according to the doctrine of Epicurus, the body consisted. These atoms were united into passages (*πόροι*) through which the juices of the body were conveyed. This doctrine, of which the developments need not further be followed, was important chiefly in so far that it was perfectly distinct from, and opposed to, the humoral pathology of Hippocrates. In the treatment of disease Asclepiades attached most importance to diet, exercise, passive movements or frictions, and the external use of cold water,—in short, to a modified athletic training. He rejected the *vis medicatrix naturæ*, pointing out that nature in many cases not only did not help but marred the cure. His knowledge of disease and surgical skill were, as appears from the accounts given by Celsus and Cœlius Aurelianus, very considerable. Asclepiades had many pupils, who adhered more or less closely to his doctrines, but it was especially one of them, Themison, who gave permanence to the teachings of his master by framing out of them, with some modifications, a new system of medical doctrine, and founding on this basis a school which lasted for some centuries in successful rivalry with the Hippocratic tradition, which, as we have seen, was up to that time the prevailing influence in medicine.

This system was known as methodism, its adherents as the methodici or methodists. Its main principles were that it was useless to consider the causes of a disease, or even the organ affected by the disease, and that it was sufficient to know what was common to all diseases, *viz.*, their common qualities (*κοινοτήτες*). Of these there were three possible forms—(1) relaxation, (2) contraction of the minute passages or *πόροι*, and (3) a mixed state, partly lax, partly constricted. The signs of these morbid states were to be found in the general constitution of the body, especially in the excretions. Besides this it was important only to consider whether the disease was acute or chronic, whether it was increasing, declining, or stationary. Treatment of disease was directed not to any special organ, nor to producing the crises and critical discharges of the Hippocratic school, but to correcting the morbid common condition or “community,” relaxing the body if it was constricted, causing contraction if it was too lax, and in the “mixed state” acting according to the predominant condition. This simple rule of treatment was the system or “method” from which the school took its name.

The methodists agreed with the empirics in one point, in their contempt for anatomy; but, strictly speaking, they were dogmatists, though with a dogma different from that of the Hippocratic school. Besides Themison, its systematic founder, the school boasted many physicians eminent in their day, among whom Thessalus of Tralles, a half-educated and boastful pretender, was one of the most popular. He reversed the Hippocratic maxim “art is long,” promising his scholars to teach them the whole of medicine in six months, and had inscribed upon his tomb *ἱατρονίκης*, as being superior to all living and bygone physicians.

In the 2d century a much greater name appears among the methodists, that of Soranus of Ephesus, a physician mentioned with praise even by Tertullian and Augustine, who practised at Rome in the reigns of Trajan and Hadrian. Soranus is known by a work, still extant in the Greek original, on the diseases of women, and also by the Latin work of Cœlius Aurelianus, three centuries later, on acute and chronic diseases, which is based upon, if not, as some think, an actual translation of, the chief

work of Soranus, and which is the principal source of our knowledge of the methodic school. The work on diseases of women is the only complete work on that subject which has come down to us from antiquity, and shows remarkable fulness of practical knowledge in relation to its subject. It is notable that an important instrument of research, the speculum, which has been reinvented in modern times, was used by Soranus; and specimens of still earlier date, showing great mechanical perfection, have been found among the ruins of Pompeii. The work on acute and chronic diseases is also full of practical knowledge, but penetrated with the theories of the methodists.

The methodic school lasted certainly for some centuries, and influenced the revival of medical science in the Middle Ages, though overshadowed by the greater reputation of Galen. It was the first definite product of Greek medicine on Roman soil, but was destined to be followed by others, which kept up a more or less successful rivalry with it, and with the Hippocratic tradition.

The so-called pneumatic school was founded by Athenæus, in the 1st century after Christ. According to its doctrines the normal as well as diseased actions of the body were to be referred to the operation of the pneuma or universal soul. This doctrine, crudely transferred from philosophical speculation, was intended to reconcile the humoral (or Hippocratic) and solidist (or methodic) schools; but the methodists seem to have claimed Athenæus as one of themselves.

The conflicts of the opposing schools, and the obvious deficiencies of each, led many physicians to try and combine the valuable parts of each system, and to call themselves eclectics. Among these were found many of the most eminent physicians of Græco-Roman times. It may be sufficient to name Rufus of Ephesus, and Archigenes, who is mentioned by Juvenal.

Although no system or important doctrine of medicine was originated by the Roman intellect, and though the practice of the profession was probably almost entirely in the hands of the Greeks, the most complete picture which we have of medical thought and activity in Roman times is due to a Latin pen, and to one who was, in all probability, not a physician. A. Cornelius Celsus, a Roman patrician, who lived probably in the first century, appears to have studied medicine as a branch of general knowledge. Whether he was a practising physician or not has been a matter of controversy. The conclusion supported by most evidence seems to be that he practised on his friends and dependants, but not as a remunerative profession. His well-known work, *De Medicina*, was one of a series of treatises intended to embrace all knowledge proper for a man of the world. It was not meant for the physicians, and was certainly little read by them, as Celsus is quoted by no medical writer, and when referred to by Pliny is spoken of as an author, not a physician. There is no doubt that his work is chiefly a compilation; and Daremberg, with other scholars, has traced a large number of passages of the Latin text to the Greek originals from which they were translated. In the description of surgical operations the vagueness of the language seems sometimes to show that the author had not performed such himself; but in other parts, and especially in his historical introduction, he speaks with more confidence; and everywhere he compares and criticizes with learning and judgment. The whole body of medical literature belonging to the Hippocratic and Alexandrian times is ably summarized, and a knowledge of the state of medical science up to and during the times of the author is thus conveyed to us which can be obtained from no other source. The work of Celsus is thus for us only second in importance to the Hippocratic writings and the works of

Galen; but it is valuable rather as a part of the history of medicine than as the subject of that history. It forms no link in the general chain of medical tradition, for the simple reason that the influence of Celsus (putting aside a few scanty allusions in mediæval times) commenced in the 15th century, when his works were first discovered in manuscript or committed to the press. Since then, however, he has been almost up to our own times the most popular and widely-read of all medical classics, partly for the qualities already indicated, partly because he was one of the few of those classics accessible to readers of Latin, and partly also because of the purity and classical perfection of his language.

Of Pliny, another encyclopædic writer, a few words must be said, though he was not a physician. In his *Natural History* we find as complete a summary of the popular medicine of his time as Celsus gives of the scientific medicine. Pliny disliked doctors, and lost no opportunity of depreciating regular medicine; nevertheless he has left many quotations from, and many details about, medical authors which are of the highest value. He is useful to us for what he wrote about the history of medicine, not for what he contributed. Like Celsus, he had little influence on succeeding medical literature or practice.

We now come to the writer who, above all others, gathered up into himself the divergent and scattered threads of ancient medicine, and out of whom again the greater part of modern European medicine has flowed. Galen (see vol. i. 803 and x. 23) was a man furnished with all the anatomical, medical, and philosophical knowledge of his time; he had studied all kinds of natural curiosities, and had stood in near relation to important political events; he possessed enormous industry, great practical sagacity, and unbounded literary fluency. He had, in fact, every quality necessary for an encyclopædic writer, or even for a literary and professional autocrat. He found the medical profession of his time split up into a number of sects, medical science confounded under a multitude of dogmatic systems, the social status and moral integrity of physicians degraded. He appears to have made it his object to reform these evils, to reconcile scientific acquirements and practical skill, to bring back the unity of medicine as it had been understood by Hippocrates, and at the same time to raise the dignity of medical practitioners.

Galen was as devoted to anatomical and, so far as then understood, physiological research as to practical medicine. He worked enthusiastically at dissection, though, the liberty of the Alexandrian schools no longer existing, he could dissect only animals, not the human body. In his anatomical studies Galen had a twofold object,—a philosophical, to show the wisdom of the Creator in making everything fit to serve its purpose, and a practical, to aid the diagnosis, or recognition, of disease. The first led him into a teleological system so minute and overstrained as to defeat its own end; the second was successfully attained by giving greater precision and certainty to medical and surgical practice in difficult cases. His general physiology was essentially founded upon the Hippocratic theory of the four elements, with which he combined the notion of spirit (pneuma) penetrating all parts, and mingled with the humours in different proportions. It was on this field that he most vehemently attacked the prevailing atomistic and materialistic views of the methodic school, and his conception of the pneuma became in some respects half metaphysical. His own researches in special branches of physiology were important, but do not strictly belong to our present subject.

The application of physiology to the explanation of diseases, and thus to practice, was chiefly by the theory of the temperaments or mixtures which Galen founded upon

the Hippocratic doctrine of humours, but developed with marvellous and fatal ingenuity. The normal condition or temperament of the body depended upon a proper mixture or proportion of the four elements—hot, cold, wet, and dry. From faulty proportions of the same arose the *intemperies* ("distempers"), which, though not diseases, were the occasions of disease. Equal importance attached to faulty mixtures or dyscrasæ of the blood. By a combination of these morbid predispositions with the action of deleterious influences from without all diseases were produced. Galen showed extreme ingenuity in explaining all symptoms and all diseases on his system. No phenomenon was without a name, no problem without a solution. And, though it was precisely in his fine-spun subtlety that he departed farthest from scientific method and practical utility, it was this very quality which seems in the end to have secured his popularity and established his pre-eminence in the medical world.

Galen's use of drugs was influenced largely by the same theories. In drugs were to be recognized the same elementary qualities—hot, cold, moist, dry, &c.—as in the human body; and, on the principle of curing by contraries, the use of one or other was indicated. The writings of Galen contain less of simple objective observation than those of several other ancient physicians, all being swept into the current of dogmatic exposition. But there is enough to show the thoroughness and extent of his practical knowledge. Unfortunately it was neither this nor his zeal for research that chiefly won him followers, but the completeness of his theoretical explanations, which fell in with the mental habits of succeeding centuries, and were such as have flattered the intellectual indolence of all ages. But the reputation of Galen grew slowly; he does not appear to have enjoyed any pre-eminence over other physicians of his time, to most of whom he was strongly opposed in opinion. In the next generation he began to be esteemed only as a philosopher; gradually his system was implicitly accepted, and it enjoyed a great though not exclusive predominance till the fall of Roman civilization. When the Arabs possessed themselves of the scattered remains of Greek culture, the works of Galen were more highly esteemed than any others except those of Aristotle. Through the Arabs the Galenical system found its way back again to Western Europe. Even when Arabian medicine gave way before the direct teaching of the Greek authors rescued from neglect, the authority of Galen was increased instead of being diminished; and he assumed a position of autocracy in medical science which was only slowly undermined by the growth of modern science in the 17th and 18th centuries.

But the history of medicine in Roman times is by no means the same thing as the history of the fate of the works of Galen. For some centuries the methodic school was popular at Rome, and produced one physician, Cœlius Aurelianus, who must be pronounced, next to Celsus, the most considerable of the Latin medical writers. His date was in all probability the end of the 4th or beginning of the 5th century. The works bearing his name are, as has been said, entirely based upon the Greek of Soranus, but are important both because their Greek originals are lost, and because they are evidence of the state of medical practice in his own time. The popularity of Cœlius is evidenced by the fact that in the 6th century an abridgment of his larger work was recommended by Cassiodorus to the Benedictine monks for the study of medicine.

Before quitting this period the name of Aretæus of Cappadocia must be mentioned. So little is known about him that even his date cannot be fixed more closely than as being between the second half of the 1st century and the beginning of the 3d. His works have been much

admired for the purity of the Greek style, and his accurate descriptions of disease; but, as he quotes no medical author, and is quoted by none before Alexander of Aphrodisias at the beginning of the 3d century, it is clear that he belonged to no school and founded none, and thus his position in the chain of medical tradition is quite uncertain. Alexander of Aphrodisias, who lived and wrote at Athens in the time of Septimius Severus, is best known by his commentaries on Aristotle, but also wrote a treatise on fevers, still extant.

*Ancient Medicine after Galen.*—The Byzantine school of medicine, which closely corresponds to the Byzantine literary and historical schools, followed closely in Galen's footsteps, and its writers were chiefly compilers and encyclopædists. The earliest is Oribasius (326–403), whose date and position are fixed by his being the friend and court physician of Julian the Apostate. He was a Greek of Pergamum, educated in Alexandria, and long resident in Byzantium. His great work *Συναγωγή ιατρικαί*, of which only about one-third has been preserved, was a medical encyclopædia founded on extracts from Hippocrates, Galen, Dioscorides, and certain Greek writers who are otherwise very imperfectly known. The work is thus one of great historical value but of no originality. The next name which requires to be mentioned is that of Aetius (550 A.D.), a compiler who closely followed Oribasius, but with inferior powers, and whose work also has an historical but no original value. A higher rank among medical writers is assigned to Alexander of Tralles (525–605), whose doctrine was that of an eclectic. His practical and therapeutical rules are evidently the fruit of his own experience, though it would be difficult to attribute to him any decided advance in medical knowledge. But the most prominent figure in Byzantine medicine is that of Paul of Ægina (Paulus Ægineta), who lived probably in the early part of the 7th century. His skill, especially in surgery, must have been considerable, and his *Ἱατρικά* gives a very complete picture of the achievements of the Greeks in this department. Another work, on obstetrics, now lost, was equally famous, and procured for him, among the Arabs, the name of "the Obstetrician." His reputation lasted through the Middle Ages, and was not less in the Arabian schools than in the West. In this respect Paulus is a most important influence in the development of medicine. His great work on surgery was early translated into Arabic, and became the foundation of the surgery of Abulcasis, which in turn (to anticipate) was one of the chief sources of surgical knowledge to Europe in the Middle Ages. The succeeding period of Byzantine history was so little favourable to science that no name worthy of note occurs again (though many medical works of this period are still extant) till the 13th century, when we meet with a group of writers;—Demetrius Pepagomenus, Nicolaus Myrepsus, and Johannes, called Actuarius, who flourished under the protection of the Palæologi. The work of the last has some independent merit; but all are interesting as showing a fusion of Greek and Arabian medicine, the latter having begun to exercise even in the 11th century a reflex influence on the schools of Byzantium. Something was borrowed even from the school of Salerno, and thus the close of Byzantine medicine is brought into connexion with the dawn of science in modern Europe.

In the West the period after Galen affords little evidence of anything but a gradual though unvarying decline in Roman medicine. Cœlius Aurelianus, already referred to as the follower of Soranus, must be mentioned as showing the persistence of the methodic school. An abridgment of one of his writings, with the title of *Aurelius*, became the most popular of all Latin medical works. As a writer he

was worthy of a better period of medical literature. Little else was produced in these times but compilations, of the most meagre kind, chiefly of the nature of herbals, or domestic receipt-books; among the authors of which it may be sufficient to name Serenus Sammonicus (3d century), Gargilius Martialis (3d century), and Marcellus Empiricus (5th century). Certain compilations still extant bear the falsely-assumed names of eminent writers, such as Pliny and Hippocrates. A writer with the (perhaps assumed) name of Apuleius Platonius produced a herbal which held its ground till the 15th century at least, and was in the 9th translated into Anglo-Saxon. These poor compilations, together with Latin translations of certain works of Galen and Hippocrates, formed a medical literature, meagre and unprogressive indeed, but of which a great part survived through the Middle Ages till the discovery of printing and revival of learning. It is important to remember that this obscure stream of tradition flowed on, only partially affected by the influx of Arabian, or even the early revival of purer classical learning.

*Arabian Medicine.*—The rise of the Mohammedan empire, which influenced Europe so deeply both politically and intellectually, made its mark also in the history of medicine. As in the parallel case of the Roman conquest of Greece, the superior culture of the conquered race asserted its supremacy over their Arab conquerors. After the Mohammedan conquests became consolidated, and learning began to flourish, schools of medicine, often connected with hospitals and schools of pharmacy, arose in all the chief seats of Moslem power. At Damascus Greek medicine was zealously cultivated with the aid of Jewish and Christian teachers. In Baghdad, under the rule of Hārūn el Rashīd and his successors, a still more flourishing school arose, where numerous translations of Greek medical works were made. The names of Mesua, or Yaḥyá ibn Māsawaih (ob. 243 A.H., 857–8 A.D.), celebrated for his knowledge of drugs, and Honein ibn Ishāq el 'Ibādī (ob. 873) or Joannitius, the translator and commentator of Hippocrates and Galen, belong to this period. Certain writings of Joannitius, translated into Latin, were popular in the Middle Ages in Europe, and were printed in the 16th century. At the same time the Arabs became acquainted with Indian medicine, and Indian physicians lived at the court of Baghdad. The Islamite rulers in Spain were not long behind those of the East in encouraging learning and medical science, and developed culture to a still higher degree of perfection. In that country much was due to the Jews, who had already established schools in places which were afterwards the seats of Moslem dominion. From the 10th to the 13th century was the brilliant period of Arabian medicine in Spain.<sup>1</sup>

The classical period of Arabian medicine begins with Rhazes (Abū Bakr Moḥammed ibn Zakariyā el-Rāzī, 313 A.H., 925–26 A.D.), a native of Ray in the province of Dailam (Persia), who practised with distinction at Baghdad; he followed the doctrines of Galen, but learnt much from Hippocrates. He was the first of the Arabs to treat medicine in a comprehensive and encyclopædic manner, surpassing probably in voluminousness Galen himself, though but a small proportion of his works are extant. Rhazes is deservedly remembered as having first described small-pox and measles in an accurate manner. Haly, i.e., 'Alī ibn el-'Abbās (ob. 994), a Persian, wrote a medical text-book, known as the "Royal Book," which was the standard authority among the Arabs up to the time of Avicenna, and was more than once translated into Latin and printed. Other writers of this century need not be mentioned here; but the next, the 11th century, is given as

the probable though uncertain date of a writer who had a great influence on European medicine, Mesua the younger of Damascus, whose personality is obscure, and of whose very existence some historians have doubted, thinking that the name was assumed by some mediæval Latin writer. The work *De Simplicibus*, which bears his name, was for centuries a standard authority on what would now be called *materia medica*, was printed in twenty-six editions in the 15th century and later, and was used in the formation of the first London pharmacopœia, issued by the College of Physicians in the reign of James I. Either to the 10th or the 11th century must be referred the name of another Arabian physician who has also attained the position of a classic, Abū'l Kāsim, or Abulcasis, of El-Zahra, near Cordova in Spain. His great work, *Altaṣrīf*, a medical encyclopædia, is chiefly valued for its surgical portion (already mentioned), which was translated into Latin in the 12th century, and was for some centuries a standard if not the standard authority on surgery in Europe. Among his own countrymen the fame and position of Abulcasis were soon eclipsed by the greater name of Avicenna (Ibn Sīnā).

Avicenna (see vol. iii. p. 152 *sq.*) has always been regarded as the chief representative of Arabian medicine. He wrote on philosophy also, and in both subjects acquired the highest reputation through the whole of Eastern Islam. In Mohammedan Spain he was less regarded, but in Europe his works even eclipsed and superseded those of Hippocrates and Galen. His style and expository power are highly praised, but the subject-matter shows little originality. The work by which he is chiefly known, the celebrated "canon," is an encyclopædia of medical and surgical knowledge, founded upon Galen, Aristotle, the later Greek physicians, and the earlier Arabian writers, singularly complete and systematic, but is thought not to show the practical experience of its author. As in the case of Galen, the formal and encyclopædic character of Avicenna's works was the chief cause of his popularity and ascendancy, though in modern times these very qualities in a scientific or medical writer would rather cause him to become more speedily antiquated.

In the long list of Arabian medical writers none can here be mentioned except the great names of the Hispano-Moorish school, a school both philosophically and medically antagonistic to that of Avicenna. Of these the earliest is Avenzoar, or Abumeron, that is, Abū Merwān 'Abd el-Malik Ibn Zohr (1113–62), a member of a family which gave several distinguished members to the medical profession. His chief work, *Al-Taysīr* (facilitatio), is thought to show more practical experience than the writings of Avicenna, and to be less based upon dialectical subtleties. It was translated into Latin, and more than once printed, as were some of his lesser works, which thus formed a part of the contribution made by the Arabians to European medicine. His friend and pupil AVERROES of Cordova (*q.v.*), so well known for his philosophical writings, was also an author in medical subjects, and as such widely read in Latin. The famous Rabbi MAIMONIDES (*q.v.*) closes for us the roll of medical writers of the Arabian school. His works exist chiefly in the original Arabic or in Hebrew translations; only some smaller treatises have been translated into Latin, so that no definite opinion can be formed as to their medical value. But, so far as is known, the independent and rationalistic spirit which the two last-named writers showed in philosophy did not lead them to take any original point of view in medicine.

The works of the Arabian medical writers who have now been mentioned form a very small fraction of the existing literature. Three hundred medical writers in

<sup>1</sup> See Dozy, *Cat. Cod. Or. Lug. Bat.*, ii. 296.

Arabic are enumerated by Wüstenfeld, and other historians have enlarged the list (Haeser), but only three have been printed in the original; a certain number more are known through old Latin translations, and the great majority still exist in manuscript. It is thus evident that the circumstance of having been translated (which may have been in some cases almost an accident) is what has chiefly determined the influence of particular writers on Western medicine. But it is improbable that further research will alter the general estimate of the value of Arabian medicine. There can be no doubt that it was in the main Greek medicine, modified to suit other climates, habits, and national tastes, and with some important additions from Oriental sources. The greater part is taken from Hippocrates, Galen, Dioscorides, and later Greek writers. The Latin medical writers were necessarily unknown to the Arabs; and this was partly the cause that even in Europe Galenic medicine assumed such a preponderance, the methodic school and Celsus being forgotten or neglected. In anatomy and physiology the Arabians distinctly went back; in surgery they showed no advance upon the Greeks; in practical medicine nothing new can be traced, except the description of certain diseases (*e.g.*, small-pox and measles) unknown or imperfectly known to the Greeks; the only real advance was in pharmacy and the therapeutical use of drugs. By their relations with the further East, the Arabs became acquainted with valuable new remedies which have held their ground till modern times; and their skill in chemistry enabled them to prepare new chemical remedies, and form many combinations of those already in use. They produced the first pharmacopœia, and established the first apothecaries' shops. Many of the names and many forms of medicines now used, and in fact the general outline of modern pharmacy, except so far as modified by modern chemistry, started with the Arabs. Thus does Arabian medicine appear as judged from a modern standpoint; but to mediæval Europe, when little but a tradition remained of the great ancient schools, it was invested with a far higher degree of originality and importance.

It is now necessary to consider what was the state of medicine in Europe after the fall of the Western empire and before the influence of Arabian science and literature began to be felt. This we may call the pre-Arabian or Salernitan period.

*Medicine in the Early Middle Ages: School of Salerno.*—In medical as in civil history there is no real break. A continuous thread of learning and practice must have connected the last period of Roman medicine already mentioned with the dawn of science in the Middle Ages. But the intellectual thread is naturally traced with greater difficulty than that which is the theme of civil history; and in periods such as that from the 5th to the 10th century in Europe it is almost lost. The chief homes of medical as of other learning in these disturbed times were the monasteries. Though the science was certainly not advanced by their labours, it was saved from total oblivion, and many ancient medical works were preserved either in Latin or vernacular versions. The "Anglo-Saxon Leechdoms" of the 11th century, published in the Master of the Rolls series of mediæval chronicles and memorials, admirably illustrate the mixture of magic and superstition with the relics of ancient science which constituted monastic medicine. Similar works, in Latin or other languages, exist in manuscript in all the great European libraries. It was among the Benedictines that the monastic study of medicine first received a new direction, and aimed at a higher standard. The study of Hippocrates, Galen, and other classics was recommended by Cassiodorus (6th century), and in the original mother-abbey of Monte Cassino medicine was

studied; but there was not there what could be called a medical school; nor had this foundation any connexion (as has been supposed) with the famous school of Salerno.

The origin of this, the most important source of medical knowledge in Europe in the early Middle Ages, is involved in obscurity. It is known that Salerno, a Roman colony, in a situation noted in ancient times for its salubrity, was in the 6th century at least the seat of a bishopric, and at the end of the 7th century of a Benedictine monastery, and that some of the prelates and higher clergy were distinguished for learning, and even for medical acquirements. But it has by recent researches been clearly established that the celebrated *Schola Salernitana* was a purely secular institution. All that can with certainty be said is that a school or collection of schools gradually grew up in which especially medicine, but also, in a subordinate degree, law and philosophy were taught. In the 9th century Salernitan physicians were already spoken of, and the city was known as *Civitas Hippocratica*. A little later we find great and royal personages resorting to Salerno for the restoration of their health, among whom was William of Normandy, afterwards the Conqueror. The number of students of medicine must at one time have been considerable, and in a corresponding degree the number of teachers. Among the latter many were married, and their wives and daughters appear also in the lists of professors. The most noted female professor was the celebrated Trotula in the 11th century. The Jewish element appears to have been important among the students, and possibly among the professors. The reputation of the school was great till the 12th or 13th century, when the introduction of the Arab medicine was gradually fatal to it. The foundation of the university of Naples, and the rise of Montpellier, also contributed to its decline.

The teachings of the Salernitan doctors are pretty well known through existing works, some of which have only recently been discovered and published. The best-known is the anonymous rhyming Latin poem on health, *Regimen Sanitatis Salerni*, professedly written for the use of the "king of England," supposed to mean Robert, son of William the Conqueror; it had an immense reputation in the Middle Ages, and was afterwards many times printed, and translated into most European languages. This was a popular work intended for the laity; but there are others strictly professional. Among the writers it may be sufficient to mention here Gariopontus; Copho, who wrote the *Anatome Porci*, a well-known mediæval book; Joannes Platearius, first of a family of physicians bearing the same name, whose *Practica*, or medical compendium, was afterwards several times printed; and Trotula, believed to be the wife of the last-named. All of these fall into the first period before the advent of Arabian medicine. In the transitional period, when the Arabian school began to influence European medicine, but before the Salernitans were superseded, comes Nicolaus Præpositus, who wrote the *Antidotarium*, a collection of formulæ for compound medicines, which became the standard work on the subject, and the foundation of many later compilations. An equally popular writer was Gilles de Corbeil (*Ægidius Corboliensis*), at one time a teacher at Salerno, afterwards court physician to Philip Augustus of France, who composed several poems in Latin hexameters on medical subjects. Two of them, on the urine and the pulse respectively, attained the position of medical classics.

None of these Salernitan works rise much above the rank of compilations, being founded on Hippocrates, Galen, and later Greek writers, with an unmistakable mixture of the doctrines of the methodists. But they often show much practical experience, and exhibit the naturalistic method of the Hippocratic school. The general plan of

treatment is dietetic rather than pharmaceutical, though the art of preparing drugs had reached a high degree of complexity at Salerno. Anatomy was as little regarded as it was in the later ancient schools, the empiric and methodic, but demonstrations of the parts of the body were given on swine. Although it cannot be said that the science of medicine was advanced at Salerno, still its decline was arrested at a time when every other branch of learning was rapidly falling into decay; and there can be no doubt that the observation of patients in hospitals, and probably clinical instruction, were made use of in learning and teaching. The school of Salerno thus forms a bridge between the ancient and the modern medicine, more direct though less conspicuous than that circuitous route, through Byzantium, Baghdad, and Cordova, by which Hippocrates and Galen, in Arabian dress, again entered the European world. Though the glory of Salerno had departed, the school actually existed till it was finally dissolved by an edict of the emperor Napoleon I. in the year 1811.

*Introduction of Arabian Medicine: The Scholastic Period.*—About the middle of the 11th century the Arabian medical writers began to be known by Latin translations in the Western world. Constantinus Africanus, a monk, was the author of the earliest of such versions (1050 A.D.); his labours were directed chiefly to the less important and less bulky Arabian authors, of whom Haly was the most noted; the real classics were not introduced till later. For some time the Salernitan medicine held its ground, and it was not till the conquest of Toledo by Alphonso of Castile that any large number of Western scholars came in contact with the learning of the Spanish Moors, and systematic efforts were made to translate their philosophical and medical works. Jewish scholars, often under the patronage of Christian bishops, were especially active in the work. In Sicily also the Oriental tendencies of Frederick Barbarossa and Frederick II. worked in the same direction. Gerard of Cremona, a physician of Toledo (1114–87), made translations, it is said by command of Barbarossa, from Avicenna and others. It is needless to point out the influence of the crusades in making Eastern ideas known in the Western world. The influence of Arabian medicine soon began to be felt even in the Hippocratic city of Salerno, and in the 13th century is said to have held an even balance with the older medicine. After this time the foreign influence predominated; and by the time that the Aristotelian dialectic, in the introduction of which the Arabs had so large a share, prevailed in the schools of Europe, the Arabian version of Greek medicine reigned supreme in the medical world. That this movement coincided with the establishment of some of the older European universities is well known. The history of medicine in the period now opening is closely combined with the history of scholastic philosophy. Both were infected with the same dialectical subtlety, which was, from the nature of the subject, especially injurious to medicine.

At the same time, through the rise of the universities, medical learning was much more widely diffused, and the first definite forward movement was seen in the school of Montpellier, where a medical faculty existed early in the 12th century, afterwards united with faculties of law and philosophy. The medical school owed its foundation largely to Jewish teachers, themselves educated in the Moorish schools of Spain, and imbued with the intellectual independence of the Averroists. Its rising prosperity coincided with the decline of the school of Salerno. Montpellier became distinguished for the practical and empirical spirit of its medicine, as contrasted with the dogmatic and scholastic teaching of Paris and other universities. In Italy, Bologna and Padua were earliest distinguished for

medical studies,—the former preserving more of the Galenical tradition, the latter being more progressive and Averroist. The northern universities contributed little,—the reputation even of Paris being of later growth.

The supremacy of Arabian medicine lasted till the revival of learning, when the study of the medical classics in their original language worked another revolution. The medical writers of this period, who chiefly drew from Arabian sources, have been called Arabists (though it is difficult to give any clear meaning to this term), and were afterwards known as the neoterics.

The medical literature of this period is extremely voluminous, but essentially second-hand, consisting mainly of commentaries on Hippocrates, Galen, Avicenna, and others, or of compilations and *compendia* still less original than commentaries. Among these may be mentioned the *Conciliator* of Peter of Abano (1250–1315), the *Aggregator* of Jacob de Dondi (1298–1359), both of the school of Padua, and the *Pandectæ Medicinæ* of the Salernitan Matthæus Sylvaticus (ob. 1342), a sort of medical glossary and dictionary. But for us the most interesting fact is the first appearance of Englishmen as authors of medical works having a European reputation, distinguished, according to the testimony of Haeser, by a practical tendency characteristic of the British race, and fostered in the school of Montpellier.

The first of these works is the *Compendium Medicinæ*, also called *Laurea* or *Rosa Anglicana*, of Gilbert (Gilbertus Anglicus, about 1290), said to contain good observations on leprosy. A more important work, the *Practica seu Lilium Medicinæ*, of Bernard Gordon, a Scottish professor at Montpellier (written in the year 1307), was more widely spread, being translated into French and Hebrew, and printed in several editions. Of these two physicians the first probably, the latter certainly, was educated and practised abroad, but John Gaddesden, the author of *Rosa Anglica seu Practica Medicinæ* (between 1305 and 1317), was a graduate in medicine of Merton College, Oxford, and court physician. His compendium is entirely wanting in originality, and perhaps unusually destitute of common sense, but it became so popular as to be reprinted up to the end of the 16th century. Works of this kind became still more abundant in the 14th and in the first half of the 15th century, till the wider distribution of the medical classics in the original put them out of fashion.

In surgery this period was far more productive than in medicine, especially in Italy and France, but the limits of our subject only permit us to mention Gulielmus de Saliceto of Piacenza (about 1275), Lanfranchi of Milan (died about 1306), the French surgeon, Guy de Chauliac (about 1350), and the Englishman, John Ardern (about 1350). In anatomy also the beginning of a new epoch was made by Mondino de Liucci, or Mundinus (1275–1326), and his followers. Some advance was made in chemistry by the celebrated Arnold de Villanova (1235–1312), whose medical writings (if the *Breviarium Practicæ* be rightly ascribed to him) rise above the rank of compilations. Finally, in the 13th and especially the 14th century, we find, under the name of *consilia*, the first mediæval reports of medical cases which are preserved in such a form as to be intelligible. Collections of *consilia* were published, among others, by Gentilis Fulgineus before 1348, by Bartolomeo Montagnana (died in 1470), and by Baverius de Baveriis of Imola (about 1450). The last-named, we can say from experience, contains much that is interesting and readable.

*Period of the Revival of Learning.*—The impulse which all departments of intellectual activity received from the revival of Greek literature in Europe was felt by medicine among the rest. Not that the spirit of the science, or of its corresponding practice, was at once changed. The

basis of medicine through the Middle Ages had been literary and dogmatic, and it was literary and dogmatic still; but the medical literature now brought to light, including as it did the more important works of Hippocrates and Galen, many of them hitherto unknown, and in addition the forgotten element of Latin medicine, especially the work of Celsus, was in itself far superior to the second-hand compilations and incorrect versions which had formerly been accepted as standards. The classical works, though still regarded with unreasoning reverence, were found to have a germinative and vivifying power that carried the mind out of the region of dogma, and prepared the way for the scientific movement which has been growing in strength up to our own day.

Two of the most important results of the revival of learning were indeed such as are excluded from the scope of this brief sketch, namely, the reawakening of anatomy, which to a large extent grew out of the study of the works of Galen, and the investigation of medicinal plants, to which a fresh impulse was given by the revival of Dioscorides and other ancient naturalists. The former brought with it necessarily a more accurate conception of physiology, and thus led up to the great discovery of Harvey, which was the turning-point in modern medicine. The latter gave rise, on the one hand, to the modern science of botany, on the other to a more rational knowledge of drugs and their uses. At the same time, the discovery of America, and increased intercourse with the East, by introducing a variety of new plants, greatly accelerated the progress both of botany and pharmacology.

But it was not in these directions that improvement was first looked for. It was at first very naturally imagined that the simple revival of classical and especially of Greek literature would at once produce the same brilliant results in medicine as in literature and philosophy. The movement of reform started, of necessity, with scholars rather than practising physicians,—more precisely with a group of learned men, whom we may be permitted, for the sake of a name, to call the medical humanists, equally enthusiastic in the cause of letters and of medicine. From both fields they hoped to expel the evils which were summed up in the word barbarism. Nearly all mediæval medical literature was condemned under this name; and for it the humanists proposed to substitute the originals of Hippocrates and Galen, thus leading back medicine to its fountain-head. Since a knowledge of Greek was still confined to a small body of scholars, and a still smaller proportion of physicians, the first task was to translate the Greek classics into Latin. To this work several learned physicians, chiefly Italians, applied themselves with great ardour. Among the earliest were Nicolaus Leoniceus of Vicenza (1428–1524), Giovanni de Monte or Montanus (1498–1552), and many others in Italy. In northern Europe should be mentioned Gulielmus Copus (1471–1532) and Günther of Andernach (1487–1584) better known as Guinterius Andernacensis, both for a time professors at Paris; and, among the greatest, Thomas Linacre (about 1460–1524; see LINACRE). A little later Janus Cornarius or Hagenbut (1500–58) and Leonard Fuchs (1501–66) in Germany, and John Kaye or Caius (1510–72) in England, carried on the work. Symphorien Champier (Champerius or Campegius) of Lyons (1472–1539), a contemporary of Rabelais, and the patron of Servetus, wrote with fantastic enthusiasm on the superiority of the Greek to the Arabian physicians, and possibly did something to enlist in the same cause the two far greater men just mentioned. Rabelais not only lectured on Galen and Hippocrates, but edited some works of the latter; and Servetus, in a little tract *Syruporum universa ratio*, defended the practice of Galen as compared with that of

the Arabians. The great Aldine press made an important contribution to the work, by *editiones principes* of Hippocrates and Galen in the original. Thus was the campaign opened against the mediæval and Arabian writers, till finally Greek medicine assumed a predominant position, and Galen took the place of Avicenna. The result was recorded in a formal manner by the Florentine Academy, sometime shortly before 1535: “quæ, excusso Arabicæ et barbaræ servitutis medicæ jugo, ex professo se Galenicam appellavit et profligato barbarorum exercitu unum totum et solum Galenum, ut optimum artis medicæ authorem, in omnibus se sequuturam pollicita est.” Janus Cornarius, from whom this is quoted, laments, however, that the Arabians still reigned in most of the schools of medicine, and that the Italian and French authors of works called *Practica* were still in high repute. The triumph of Galenism was therefore not complete by the middle of the 16th century. It was probably most so, and earliest, in the schools of Italy and in those of England, where the London College of Physicians might be regarded as an offshoot of the Italian schools. Paris was the stronghold of conservatism, and Germany was stirred by the teachings of one who must be considered apart from all schools—Paracelsus. The nature of the struggle between the rival systems may be well illustrated by a formidable controversy about the rules for bleeding in acute diseases. This operation, according to the Arabian practice, was always performed on a vein at a distance from the organ affected. The Hippocratic and also Galenic rule, to let blood from, or near to, the diseased organ, was revived by Brissot (1470–1522), a professor in the university of Paris. His attempt at reform, which was taken to be, as in effect it was, a revolt against the authority of the Arabian masters, led to his expulsion from Paris, and the formal prohibition by the parliament of his method. Upon this apparently trifling question arose a controversy which lasted many years, occupied several universities, and led to the interposition of personages no less important than the pope and the emperor, but which is thought to have largely contributed to the final downfall of the Arabian medicine.

*Paracelsus and Chemical Medicine.*—Contemporary with the school of medical humanists, but little influenced by them, lived in Germany a man of strange genius, of whose character and importance the most opposite opinions have been expressed. The first noticeable quality in Paracelsus (c. 1490–1541) is his revolutionary independence of thought, which was supported by his immense personal arrogance. Himself well trained in the learning and medical science of the day, he despised and trampled upon all traditional and authoritative teachings. He began his lectures at Basel by burning the books of Avicenna and others; he afterwards boasted of having read no books for ten years; he protested that his shoe buckles were more learned than Galen and Avicenna. On the other hand, he spoke with respect of Hippocrates, and wrote a commentary on his *Aphorisms*. In this we see a spirit very different from the enthusiasm of the humanists for a purer and nobler philosophy than the scholastic and Arabian versions of Greek thought. There is no record of Paracelsus's knowledge of Greek, and as, at least in his student days, the most important works of Greek medicine were very imperfectly known, it is probable he had little first-hand acquaintance with Galen or Hippocrates, while his breach with the humanists is the more conspicuous from his lecturing and writing chiefly in his native German.

Having thus made a clean sweep of nearly the whole of the dogmatic medicine, what did Paracelsus put in its place? Certainly not pure empiricism, or habits of objective observation. He had a dogma of his own,—one founded, according to his German expositors, on the views of the

Neo-Platonists, of which a few disjointed specimens must here suffice. The human body was a "microcosm" which corresponded to the "macrocosm," and contained in itself all parts of visible nature,—sun, moon, stars, and the poles of heaven. To know the nature of man and how to deal with it, the physician should study, not anatomy, which Paracelsus utterly rejected, but all parts of external nature. Life was a perpetual germinative process controlled by the indwelling spirit or Archeus; and diseases, according to the mystical conception of Paracelsus, were not natural, but spiritual. Nature was sufficient for the cure of most diseases; art had only to interfere when the internal physician, the man himself, was tired or incapable. Then some remedy had to be introduced which should be antagonistic, not to the disease in a physical sense, but to the spiritual seed of the disease. These remedies were *arcana*,—a word corresponding partly to what we now call specific remedies, but implying a mysterious connexion between the remedy and the "essence" of the disease. *Arcana* were often shown to be such by their physical properties, not only by such as heat, cold, &c., but by fortuitous resemblances to certain parts of the body; thus arose the famous doctrine of "signatures," or signs indicating the virtues and uses of natural objects, which was afterwards developed into great complexity. Great importance was also attached to chemically prepared remedies as containing the essence or spiritual quality of the material from which they were derived. The actual therapeutical resources of Paracelsus included a large number of metallic preparations, in the introduction of some of which he did good service, and, among vegetable preparations, the tincture of opium, still known by the name he gave it, laudanum. In this doubtless he derived much advantage from his knowledge of chemistry, though the science was as yet not disentangled from the secret traditions of alchemy, and was often mixed up with imposture.

German historians of medicine attach great importance to the revolt of Paracelsus against the prevailing systems, and trace in his writings anticipations of many scientific truths of later times. That his personality was influential, and his intrepid originality of great value as an example in his own country, is undeniable. As a national reformer he has been not inaptly compared to Luther. But his importance in the universal history of medicine we cannot estimate so highly. The chief immediate result we can trace is the introduction of certain mineral remedies, especially antimony, the use of which became a kind of badge of the disciples of Paracelsus. The use of these remedies was not, however, necessarily connected with a belief in his system, which seems to have spread little beyond his own country. Of the followers of Paracelsus some became mere mystical quacks and impostors. Others, of more learning and better repute, were distinguished from the regular physicians chiefly by their use of chemical remedies. In France the introduction of antimony gave rise to a bitter controversy which lasted into the 17th century, and led to the expulsion of some men of mark from the Paris faculty. In England "chemical medicine" is first heard of in the reign of Elizabeth, and was in like manner contemned and assailed by the College of Physicians and the Society of Apothecaries. But it should be remembered that all the chemical physicians did not call Paracelsus master. The most notorious of that school in England, a certain Anthony, never quotes Paracelsus, but relies upon Arnold de Villanova and Raymund Lully. From this time, however, it is always possible to trace a school of chemical practitioners, who, though condemned by the orthodox Galenists, held their ground, till in the 17th century a successor of Paracelsus arose in the celebrated Van Helmont.

*Consequences of the Revival of Ancient Medicine.*—The revival of Galenic and Hippocratic medicine, though ultimately it conferred the greatest benefits on medical science, did not immediately produce any important or salutary reform in practical medicine. The standard of excellence in the ancient writers was indeed far above the level of the 16th century; but the fatal habit of taking at second hand what should have been acquired by direct observation retarded progress more than the possession of better models assisted it, so that the fundamental faults of mediæval science remained uncorrected.

Nevertheless some progress has to be recorded, even if not due directly to the study of ancient medicine. In the first place the 15th and 16th centuries were notable for the outbreak of certain epidemic diseases, which were unknown to the old physicians. Of these the chief was the "sweating sickness" or "English sweat," especially prevalent in, though not confined to, the country whence it is named. Among many descriptions of this disease, that by John Kaye or Caius, already referred to, was one of the best, and of great importance as showing that the works of Galen did not comprise all that could be known in medicine. The spread of syphilis, a disease equally unknown to the ancients, and the failure of Galen's remedies to cure it, had a similar effect.

In another direction the foundations of modern medicine were being laid during the 16th century, namely, by the introduction of clinical instruction in hospitals. In this Italy, and especially the renowned school of Padua, took the first step, where De Monte (Montanus), already mentioned as a humanist, gave clinical lectures on the patients in the hospital of St Francis, which may still be read with interest. Pupils flocked to him from all European countries; Germans are especially mentioned; a Polish student reported and published some of his lectures; and the Englishman Kaye was a zealous disciple, who does not, however, seem to have done anything towards transplanting this method of instruction to his own country. Inspections of the dead, to ascertain the nature of the disease, were made, though not without difficulty, and thus the modern period of the science of morbid anatomy was ushered in.

*Medicine in the 17th century.*—The medicine of the early part of the 17th presents no features to distinguish it from that of the preceding century. The practice and theory of medicine were mainly founded upon Hippocrates and Galen, with ever-increasing additions from the chemical school. But the development of mathematical and physical science soon introduced a fundamental change in the habits of thought with respect to medical doctrine.

These discoveries not only weakened or destroyed the respect for authority in matters of science, but brought about a marked tendency to mechanical explanations of life and disease. When Harvey by his discovery of the circulation furnished an explanation of many vital processes which was reconcileable with the ordinary laws of mechanics, the efforts of medical theorists were naturally directed to bringing all the departments of medicine under similar laws. It is often assumed that the writings and influence of Bacon did much towards introducing a more scientific method into medicine and physiology. But, without discussing the general philosophical position or historical importance of Bacon, it may safely be said that his direct influence can be little traced in medical writings of the first half of the 17th century. Harvey, as is well known, spoke slightly of the great chancellor, and it is not till the rapid development of physical science in England and Holland in the latter part of the century, that we find Baconian principles explicitly recognized.

The dominant factors in the 17th century medicine were

the discovery of the circulation by Harvey (published in 1628), the mechanical philosophy of Descartes and the contemporary progress of physics, the teaching of Van Helmont and the introduction of chemical explanations of morbid processes, and finally, combined of all these, and inspiring them, the rise of the spirit of inquiry and innovation, which may be called the scientific movement. Before speaking in detail of these, we may note that by other influences, quite independent of theories, important additions were made to practical medicine. The method of clinical instruction in hospitals, commenced by the Italians, was introduced into Holland, where it was greatly developed, especially at Leyden, in the hands of the celebrated Sylvius. It is noteworthy that concurrently with the rise of clinical study the works of Hippocrates were more and more valued, while Galen began to sink into the background.

At the same time the discovery of new diseases, unknown to the ancients, and the keener attention which the great epidemics of plague caused to be paid to those already known, led to more minute study of the natural history of disease. The most important disease hitherto undescribed was rickets, first made known by Arnold de Boot, a Frisian who practised in Ireland, in 1649, and afterwards more fully in the celebrated work of Glisson in 1651. The plague was carefully studied by Diemerbroek (*De Peste*, 1646) and others. Hodges, of London, in 1665 seems to have been the first who had the courage to make a post-mortem inspection of a plague patient. Bennet wrote an important work on consumption in 1654. During the same period many new remedies were introduced, the most important being cinchona bark, brought to Spain in the year 1640. The progress of pharmacy was shown by the publication of *Dispensatories* or *Pharmacopœiæ*, such as that of the Royal College of Physicians of London in 1618. This, like the earlier German works of the same kind (on which it was partly founded), contains both the traditional (Galenical) and the modern or chemical remedies.

*Van Helmont.*—The medicine of the 17th century was especially distinguished by the rise of systems; and we must first speak of an eccentric genius who endeavoured to construct a system for himself, as original and opposed to tradition as that of Paracelsus. Van Helmont (1578–1644) was a man of noble family in Brussels, who, after mastering all other branches of learning as then understood, devoted himself with enthusiasm to medicine and chemistry. By education and position a little out of the regular lines of the profession, he took up in medicine an independent attitude. Well acquainted with the doctrines of Galen, he rejected them as thoroughly as Paracelsus did, and borrowed from the latter some definite ideas as well as his revolutionary spirit. The archeus of Paracelsus appears again, but with still further complications,—the whole body being controlled by the *archeus influus*, and the organ of the soul and its various parts by the *archei insiti*, which are subject to the central archeus. Many of the symptoms of diseases were caused by the passions and perturbations of the archeus, and medicines acted by modifying the *ideas* of the same archeus. These and other notions cannot be here stated at sufficient length to be intelligible. It is enough to say that on this fantastic basis Helmont constructed a medical system which had some practical merits, that his therapeutical methods were mild and in many respects happy, and that he did service by applying newer chemical methods to the preparation of drugs. He thus had some share, though a share not generally recognized, in the foundation of the iatro-chemical school, now to be spoken of. But his avowed followers formed a small and discredited sect, which, in England at least, can be clearly traced in the latter part of the century.

*Discovery of the Circulation of the Blood.*—The influence of Harvey's discovery began to be felt before the middle of the century. Its merits were recognized by Descartes, among the first, nine years after its publication. For the history of the discovery, and its consequences in anatomy and physiology, we must refer to the article HARVEY. In respect of practical medicine, much less effect was at first noticeable. But this example, combined with the Cartesian principles, set many active and ingenious spirits to work to reconstruct the whole of medicine on a physiological or even a mechanical basis,—to endeavour to form what we should now call physiological or scientific medicine. The result of this was not to eliminate dogma from medicine, though it weakened the authority of the old dogma. The movement led rather to the formation of schools or systems of thought, which under various names lasted on into the 18th century, while the belief in the utility or necessity of schools and systems lasted much longer. The most important of these were the so-called iatro-physical or mechanical and the iatro-chemical schools.

*Iatro-Physical School.*—The iatro-physical school of medicine grew out of physiological theories. Its founder is held to have been Borelli of Naples (1608–79), whose treatise *De motu animalium*, published in 1680, is regarded as marking an epoch in physiology. The tendency of the school was to explain the actions and functions of the body on physical and especially on mechanical principles. The movements of bones and muscles were referred to the theory of levers; the process of digestion was regarded as essentially a process of trituration; nutrition and secretion were shown to be dependent upon the tension of the vessels, and so forth. The developments of this school belong rather to the history of physiology, where they appear, seen in the light of modern science, as excellent though premature endeavours in a scientific direction. But the influence of these theories on practical medicine was not great. The more judicious of the mechanical or physical school refrained, as a judicious modern physiologist does, from too immediate an application of their principles to daily practice. Mechanical theories were introduced into pathology, in explanation of the processes of fever and the like, but had little or no influence on therapeutics. The most important men in this school after Borelli were Steno (1638–86), Baglivi (1673–1707), and Bellini (1643–1704). An English physician, Cole (1660–1700), is also usually ranked with them. One of the most elaborate developments of the system was that of Pitcairn, a Scottish physician who became professor at Leyden (1652–1713), to be spoken of hereafter.

*Iatro-Chemical School.*—The so-called iatro-chemical school stood in a much closer relation to practical medicine than the iatro-physical. The principle which mainly distinguished it was not merely the use of chemical medicines in addition to the traditional, or, as they were called in distinction, "Galenical" remedies, but a theory of pathology or causation of disease entirely different from the prevailing "humoral" pathology. Its chief aim was to reconcile the new views in physiology and chemistry with practical medicine. In some theoretical views, and in the use of certain remedies, the school owed something to Van Helmont and Paracelsus, but took in the main an independent position. The founder of the iatro-chemical school was Francis de le Boë, called Sylvius (1614–72), belonging to a French family settled in Holland. Sylvius was for fourteen years professor of medicine at Leyden, where he attracted students from all quarters of Europe. He made a resolute attempt to reconstruct medicine on the two bases of the doctrine of the circulation of the blood and the new views of chemistry. Fermentation, which was supposed to take place in the stomach, played an important

part in the vital processes. Chemical disturbances of these processes, called *acridities*, &c., were the cause of fevers and other diseases. Sometimes acid sometimes alkaline properties predominated in the juices and secretions of the body, and produced corresponding disturbances. In nervous diseases disturbances of the vital "spirits" were most important. Still in some parts of his system Sylvius shows an anxiety to base his pathology on anatomical changes. The remedies he employed were partly Galenical, partly chemical. He was very moderate in the use of bleeding.

The doctrines of Sylvius became widely spread in Holland and Germany; less so in France and Italy. In England they were not generally accepted, till adopted with some modifications by Thomas Willis the great anatomist (1622-75), who is the chief English representative of the chemical school. Willis was as thorough-going a chemist as Sylvius. He regarded all bodies, organic and inorganic, as composed of the three elements—spirit, sulphur, and salt, the first being only found abundantly in animal bodies. The "intestinal movement of particles" in every body, or fermentation, was the explanation of many of the processes of life and disease. The sensible properties and physical alterations of animal fluids and solids depended upon different proportions, movements, and combinations of these particles. The elaborate work *Pharmacentice Rationalis*, based on these materials, had much influence in its time, though it was soon forgotten. But some parts of Willis's works, such as his descriptions of nervous diseases, and his account (the earliest) of diabetes, are classical contributions to scientific medicine. In the application of chemistry to the examination of secretions Willis made some important steps. The chemical school met with violent opposition, partly from the adherents of the ancient medicine, partly from the iatro-mechanical school. Towards the end of the 17th century appeared an English medical reformer who sided with none of these schools, but may be said in some respects to have surpassed and dispensed with them.

*Sydenham and Locke.*—Thomas Sydenham (1624-89) was educated at Oxford and at Montpellier. He was well acquainted with the works of the ancient physicians, and probably fairly so with chemistry. Of his knowledge of anatomy nothing definite can be said, as he seldom refers to it. His main avowed principle was to do without hypothesis, and study the actual diseases in an unbiassed manner. As his model in medical methods, Sydenham repeatedly and pointedly refers to Hippocrates, and he has not unfairly been called the English Hippocrates. He resembled his Greek master in the high value he set on the study of the "natural history of disease"; in the importance he attached to "epidemic constitution," that is, to the influence of weather and other natural causes in modifying disease; and further in his conception of the healing power of nature in disease, a doctrine which he even expanded beyond the teaching of Hippocrates. According to Sydenham, a disease is nothing more than an effort of nature to restore the health of the patient by the elimination of the morbid matter. The extent to which his practice was influenced by this and other *a priori* conceptions prevents us from classing Sydenham as a pure empiric, but he had the rare merit of never permitting himself to be enslaved even by his own theories. Still less was his mind warped by either of the two great systems, the classical and the chemical, which then divided the medical world. Sydenham's influence on European medicine was very great. His principles were welcomed as a return to nature by those who were weary of theoretical disputes. He introduced a milder and better way of treating fevers, especially small-pox, and gave strong support to the use of specific medicines, especially Peruvian bark. He was

an advocate of bleeding, and often carried it to excess. Another important point in Sydenham's doctrine is his clear recognition of many diseases as being what would be now called *specific*, and not due merely to an alteration in the primary qualities or humours of the older schools. From this springs his high appreciation of specific medicines.

One name should always be mentioned along with Sydenham—that of his friend John Locke. The great sensational philosopher was a thoroughly trained physician, and practised privately. He shared and defended many of Sydenham's principles, and in the few medical observations he has left shows himself to be even more thorough-going than the "English Hippocrates." It is deeply to be regretted in the interests of medicine that he did not write more. It is, however, reasonable to suppose that his commanding intellect often makes itself felt in the words of Sydenham. One sentence of Locke's in a letter to W. Molyneux sums up the practical side of Sydenham's teaching.

"You cannot imagine how far a little observation carefully made by a man not tied up to the four humours [Galen], or sal, sulphur, and mercury [Paracelsus], or to acid and alkali [Sylvius and Willis] which has of late prevailed, will carry a man in the curing of diseases though very stubborn and dangerous; and that with very little and common things, and almost no medicine at all."

We thus see that, while the great anatomists, physicists, and chemists, men of the type of Willis, Borelli, and Boyle, were laying foundations which were later on built up into the fabric of scientific medicine, little good was done by the premature application of their half-understood principles to practice. The reform of practical medicine was effected by men who aimed at, and partly succeeded in, rejecting all hypothesis and returning to the unbiassed study of natural processes, as shown in health and disease.

Sydenham showed that these processes might be profitably studied and dealt with without explaining them; and, by turning men's minds away from explanations and fixing them on facts, he enriched medicine with a *method* more fruitful than any discoveries in detail. From this time forth the reign of canonical authority in medicine was at an end, though the dogmatic spirit long survived.

*The 18th century.*—The medicine of the 18th century is notable, like that of the latter part of the 17th, for the striving after complete theoretical systems. The influence of the iatro-physical school was by no means exhausted; and in England, especially through the indirect influence of Newton's great astronomical generalizations, it took on a mathematical aspect, and is sometimes known as iatro-mathematical. This phase is most clearly developed in Pitcairn (1652-1713), who, though a determined opponent of metaphysical explanations, and of the chemical doctrines, gave to his own rude mechanical explanations of life and disease almost the dogmatic completeness of a theological system. His countryman and pupil, George Cheyne, who lived some years at Bath, published a new theory of fevers on the mechanical system, which had a great reputation. Their English contemporaries and successors, Freind, Cole, and Mead, leaned also to mechanical explanations, but with a distrust of systematic theoretical completeness, which was perhaps partly a national characteristic, partly the result of the teaching of Sydenham and Locke. Freind (1675-1728) in his *Emmenologia* gave a mechanical explanation of the phenomena of menstruation. He is also one of the most distinguished writers on the history of medicine. Cole (see above) published mechanical hypotheses concerning the causation of fevers which closely agree with those of the Italian iatro-mechanical school. More distinguished in his own day than any of these was Richard Mead (1673-1754), one of the most accomplished and socially successful physicians of modern times. Mead was the pupil of the equally popular and successful John Radcliffe

(1650-1714), who had acquired from Sydenham a contempt for book learning, and belonged to no school in medicine but the school of common sense. Radcliffe left, however, no work requiring mention in a history of medicine. Mead, a man of great learning and intellectual activity, was an ardent advocate of the mathematical doctrines. "It is very evident," he says, "that all other means of improving medicine have been found ineffectual, by the stand it was at for two thousand years, and that, since mathematicians have set themselves to the study of it, men already begin to talk so intelligibly and comprehensibly, even about abstruse matters, that it is to be hoped that mathematical learning will be the distinguishing mark of a physician and a quack." His *Mechanical Account of Poisons*, in the first edition (1702), gave an explanation of the effects of poisons, as acting only on the blood. Afterwards he modified his hypothesis, and referred the disturbances produced to the "nervous liquor," which he supposed to be a quantity of the "universal elastic matter" diffused through the universe, by which Newton explained the phenomena of light, *i.e.*, what was afterwards called the luminiferous ether. Mead's treatise on *The Power of the Sun and Moon over Human Bodies* (1704), equally inspired by Newton's discoveries, was a premature attempt to assign the influence of atmospheric pressure and other cosmical causes in producing disease. His works contain, however, many original experiments, and excellent practical observations. James Keill (1673-1719) applied Newtonian and mechanical principles to the explanation of bodily functions with still greater accuracy and completeness; but his researches have more importance for physiology than for practical medicine.

*Boerhaave*.—None of these men founded a school,—a result due in part to their intellectual character, in part to the absence in England of medical schools equivalent in position and importance to the universities of the Continent. An important academical position was, on the other hand, one of the reasons why a physician not very different in his way of thinking from the English physicians of the age of Queen Anne was able to take a far more predominant position in the medical world. Hermann Boerhaave (1668-1738) was emphatically a great teacher. He was for many years professor of medicine at Leyden, where he lectured five hours a day, and excelled in influence and reputation, not only his greatest forerunners, Montanus of Padua and Sylvius of Leyden, but probably every subsequent teacher. The hospital of Leyden, though with only twelve beds available for teaching, became the centre of medical influence in Europe. Many of the leading English physicians of the 18th century studied there; Van Swieten, a pupil of Boerhaave, transplanted the latter's method of teaching to Vienna, and founded the noted Vienna school of medicine. As the organizer, and almost the constructor, of the modern method of clinical instruction, the services of Boerhaave to the progress of medicine were immense, and can hardly be overrated. In his teaching, as in his practice, he avowedly followed the method of Hippocrates and Sydenham, both of whom he enthusiastically admired. In his medical doctrines he must be pronounced an eclectic, though taking his stand mainly on the iatro-mechanical school. The best known parts of Boerhaave's system are his doctrines of inflammation, obstruction, and "plethora." By the last-named especially he was long remembered. His object was to make all the anatomical and physiological acquisitions of his age, even microscopical anatomy, which he diligently studied, available for use in the practice of medicine. He thus differed from Sydenham, who took almost as little account of modern science as of ancient dogma. Boerhaave may be in some respects compared to Galen, but again differed from him in

that he always abstained from attempting to reduce his knowledge to a uniform and coherent system. Boerhaave attached great importance to the study of the medical classics, but rather treated them historically than quoted them as canonical authorities. It almost follows from the nature of the case that the great task of Boerhaave's life, a synthesis of ancient and modern medicine, and the work in which this is chiefly contained, his celebrated *Institutions*, could not have any great permanent value. Nearly the same thing is true even of the *Aphorisms*, in which, following the example of Hippocrates, he endeavoured to sum up the results of his long experience.

*Hoffmann and Stahl*.—We have now to speak of two writers in whom the systematic tendency of the 18th century showed itself most completely.

Friedrich Hoffmann (1660-1742), like Boerhaave, owed his influence, and perhaps partly his intellectual characteristics, to his academical position. He was in 1693 appointed the first professor of medicine in the university of Halle, then just founded by the elector Frederick III. Here he became, as did his contemporary and rival Stahl, a popular and influential teacher, though their university had not the European importance of Leyden. Hoffmann's "system" was apparently intended to reconcile the opposing "spiritual" and "materialistic" views of nature, and is thought to have been much influenced by the philosophy of Leibnitz. His medical theories rest upon a complete theory of the universe. Life depended upon a universally diffused ether, which animals breathe in from the atmosphere, and which is contained in all parts of the body. It accumulates in the brain, and there generates the "nervous fluid" or *pneuma*,—a theory closely resembling that of Mead on the "nervous liquor," unless indeed Mead borrowed it from Hoffmann. On this system are explained all the phenomena of life and disease. Health depends on the maintenance of a proper "tone" in the body,—some diseases being produced by excess of tone, or "spasm"; others by "atony," or want of tone. But it is impossible here to follow its further developments. Independently of his system, which has long ceased to exert any influence, Hoffmann made some contributions to practical medicine; and his great knowledge of chemistry enabled him to investigate the subject of mineral waters. He was equally skilful in pharmacy, but lowered his position by the practice, which would be unpardonable in a modern physician, of trafficking in secret remedies. Some of these are even to this day sold for the benefit of the orphanage at Halle.

George Ernest Stahl (1660-1734) was for more than twenty years professor of medicine at Halle, and thus a colleague of Hoffmann, whom he resembled in constructing a complete theoretical system, though their systems had little or nothing in common. Stahl's chief aim was to oppose materialism. For mechanical conceptions he substituted the theory of "animism,"—attributing to the soul the functions of ordinary animal life in man, while the life of other creatures was left to mechanical laws. The symptoms of disease were explained as efforts of the soul to rid itself from morbid influences, the soul acting reasonably with respect to the end of self-preservation. The anima thus corresponds partly to the "nature" of Sydenham, while in other respects it resembles the archeus of Van Helmont. Animism in its completeness met with little acceptance during the lifetime of its author, but influenced some of the iatro-physical school. Stahl was the author of the theory of "phlogiston" in chemistry, which in its day had great importance.

*Haller and Morgagni*.—From the subtleties of rival systems it is a satisfaction to turn to two movements in the medicine of the 18th century which, though they did not extinguish the spirit of system-making, opened up paths of

investigation by which the systems were ultimately superseded. These are physiology in the modern sense, as dating from Haller, and pathological anatomy, as dating from Morgagni.

Albrecht von Haller (1708-77) was a man of even more encyclopædic attainments than Boerhaave. He advanced chemistry, botany, anatomy, as well as physiology, and was incessantly occupied in endeavouring to apply his scientific studies to practical medicine, thus continuing the work of his great teacher Boerhaave. Besides all this he was probably more profoundly acquainted with the literature and bibliography of medicine than any one before or since. Haller occupied in the new university of Göttingen (founded 1737) a position corresponding to that of Boerhaave at Leyden, and in like manner influenced a very large circle of pupils. The appreciation of his work in physiology belongs to the history of that science; we are only concerned here with its influence on medicine. Haller's definition of irritability as a property of muscular tissue, and its distinction from sensibility as a property of nerves, struck at the root of the prevailing hypothesis respecting animal activity. It was no longer necessary to suppose that a half conscious "anima" was directing every movement. Moreover, Haller's views did not rest on a *priori* speculation, but on numerous experiments. He was among the first to investigate the action of medicines on healthy persons. Unfortunately the lesson which his contemporaries learnt was not the importance of experiment, but only the need of contriving other "systems" less open to objection; and thus the influence of Haller led directly to the theoretical subtleties of Cullen and John Brown, and only indirectly and later on to the general anatomy of Bichat. The great name of Haller does not therefore occupy a very prominent place in the history of practical medicine.

The work of Giovanni Battista Morgagni (1682-1771) had and still preserves a permanent importance beyond that of all the contemporary theorists. In a series of letters *De sedibus et causis morborum per anatomen indagatis*, published when he was in his eightieth year, he describes the appearances met with at the post-mortem examination as well as the symptoms during life in a number of cases of various diseases. It was not the first work of the kind. Bonet had published his *Sepulchretum* in 1679; and observations of post-mortem appearances had been made by Montanus, Tulp, Vieussens, Valsalva, Lancisi, Haller, and others. But never before was so large a collection of cases brought together, described with such accuracy, or illustrated with equal anatomical and medical knowledge. Morgagni's work at once made an epoch in the science. Morbid anatomy now became a recognized branch of medical research, and the movement was started which has lasted till our own day.

The contribution of Morgagni to medical science must be regarded as in some respects the counterpart of Sydenham's. The latter had, in neglecting anatomy, neglected the most solid basis for studying the natural history of disease; though perhaps it was less from choice than because his practice, as he was not attached to a hospital, gave him no opportunities. But it is on the combination of the two methods, that of Sydenham and of Morgagni, that modern medicine rests; and it is through these that it has been able to make steady progress in its own field, independently of the advance of physiology or other sciences.

The method of Morgagni found many imitators, both in his own country and in others. In England the first important name in this field is at the same time that of the first writer of a systematic work in any language on morbid anatomy, Matthew Baillie (1761-1823), who published his treatise in 1793.

*Cullen and Brown.*—It remains to speak of two system-

atic writers on medicine in the 18th century, whose great reputation prevents them from being passed over, though their real contribution to the progress of medicine was not great—Cullen and Brown.

William Cullen (1712-90) was a most eminent and popular professor of medicine at Edinburgh. The same academical influences as surrounded the Dutch and German founders of systems were doubtless partly concerned in leading him to form the plan of a comprehensive system of medicine. Cullen's system was largely based on the new physiological doctrine of irritability, but is especially noticeable for the importance attached to nervous action. Thus even gout was regarded as a "neurosis." These pathological principles of Cullen are contained in his *First Lines of the Practice of Physic*, an extremely popular book, often reprinted and translated. More importance is to be attached to his *Nosology or Classification of Diseases*. The attempt to classify diseases on a natural-history plan was not new, having been commenced by Sauvages and others, and is perhaps not a task of the highest importance. Cullen drew out a classification of great and needless complexity, the chief part of which is now forgotten, but several of his main divisions are still preserved.

It is difficult to form a clear estimate of the importance of the last systematizer of medicine, John Brown (1735-88), for, though in England he has been but little regarded, the wide though short-lived popularity of his system on the Continent shows that it must have contained some elements of brilliancy, if not originality. His theory of medicine professed to explain the processes of life and disease, and the methods of cure, upon one simple principle,—that of the property of "excitability," in virtue of which the "exciting powers," defined as being (1) external forces and (2) the functions of the system itself, call forth the vital phenomena "sense, motion, mental function, and passion." All exciting powers are stimulant, the apparent debilitating or sedative effect of some being due to a deficiency in the degree of stimulus; so that the final conclusion is that "the whole phenomena of life, health as well as disease, consist in stimulus and nothing else." Brown recognized some diseases as *sthenic*, others as *asthenic*, the latter requiring stimulating treatment, the former the reverse; but his practical conclusion was that 97 per cent. of all diseases required a "stimulating" treatment. In this he claimed to have made the most salutary reform because all physicians from Hippocrates had treated diseases by depletion and debilitating measures with the object of curing by elimination. It would be unprofitable to attempt a complete analysis of the Brunonian system; and it is difficult now to understand why it attracted so much attention in its day. To us at the present time it seems merely a dialectical construction, having its beginning and end in definitions, the words power, stimulus, &c., being used in such a way as not to correspond to any precise physical conceptions, still less to definite material objects or forces. One recommendation of the system was that it favoured a milder system of treatment than was at that time in vogue; Brown may be said to have been the first advocate of the modern stimulant or feeding treatment of fevers. He advocated the use of "animal soups" or beef tea. Further he had the discernment to see that certain symptoms, such as convulsions and delirium, which were then commonly held always to indicate inflammation, were often really signs of weakness.

The fortunes of Brown's system (called, from having been originally written in Latin, the Brunonian) form one of the strangest chapters in the history of medicine. In Scotland, Brown so far won the sympathy of the students that riotous conflicts took place between his partisans and opponents. In England his system took little root. In Italy, on the other hand, it received enthusiastic support, and, naturally,

a corresponding degree of opposition. The most important adherent to Brown's system was Rasori (1763-1837), who taught it as professor at Pavia, but afterwards substituted his own system of contra-stimulus. The theoretical differences between this and the "stimulus" theory need not be expounded. The practical difference in the corresponding treatment was very great, as Rasori advocated a copious use of bleeding and of depressing remedies, such as antimony. Joseph Frank, a German, professor at Pavia, afterwards of Vienna, the author of an encyclopædic work on medicine now forgotten, embraced the Brunonian system, though he afterwards introduced some modifications, and transplanted it to Vienna. Many names are quoted as partisans or opponents of the Brunonian system in Italy, but scarcely one of them has any other claim to be remembered. In Germany the new system called forth, a little later, no less enthusiasm and controversial heat. Girtanner first began to spread the new ideas (though giving them out as his own), but Weikard was the first avowed advocate of the system. Röschlaub (1768-1835) modified Brown's system into the theory of excitement (*Erregungstheorie*), which for a time was extremely popular in Germany. The enthusiasm of the younger Brunonians in Germany was as great as in Edinburgh or in Italy, and led to serious riots in the university of Göttingen. In America the system was enthusiastically adopted by a noted physician, Benjamin Rush, of Philadelphia, who was followed by a considerable school. France was not more influenced by the new school than England. In both countries the tendency towards positive science and progress by objective investigation was too marked for any theoretical system to have more than a passing influence. In France, however, the influence of Brown's theories is very clearly seen in the writings of Broussais, who, though not rightly classed with the system-makers, since his conclusions were partly based upon anatomical investigation, resembled them in his attempt to unite theory and practice in one comprehensive synthesis. The explanation of the meteoric splendour of the Brunonian system in other countries seems to be as follows. In Italy the period of intellectual decadence had set in, and no serious scientific ardour remained to withstand the novelties of abstract theory. In Germany the case was somewhat different. Intellectual activity was not wanting, but the great achievements of the 18th century in philosophy and the moral sciences had fostered a love of abstract speculation; and some sort of cosmical or general system was thought indispensable in every department of special science. Hence another generation had to pass away before Germany found herself on the level, in scientific investigation, of France and England.

Before the theoretic tendency of the 18th century was quite exhausted, it displayed itself in a system which, though in some respects isolated in the history of medicine, stands nearest to that of Brown,—that, namely, of Hahnemann (see HOMŒOPATHY). Hahnemann (1753-1844) was in conception as revolutionary a reformer of medicine as Paracelsus. He professed to base medicine entirely on a knowledge of symptoms, regarding all investigation of the causes of symptoms as useless. While thus rejecting all the lessons of morbid anatomy and pathology, he put forward views respecting the causes of disease which hardly bear to be seriously stated. All chronic maladies result either from three diseases—psora (the itch), syphilis, or sycosis (a skin disease), or else are maladies produced by medicines. Seven-eighths of all chronic diseases are produced by itch driven inwards.<sup>1</sup> (It is fair to say that

these views were published in one of his later works.) In treatment of disease Hahnemann rejected entirely the notion of a *vis medicatrix naturæ*, and was guided by his well-known principle "*similia similibus curantur*," which he explained as depending on the law that in order to get rid of a disease some remedy must be given which should substitute for the disease an action dynamically similar, but weaker. The original malady being thus got rid of, the vital force would easily be able to cope with and extinguish the slighter disturbance caused by the remedy. Something very similar was held by Brown, who taught that "indirect debility" was to be cured by a lesser degree of the same stimulus as had caused the original disturbance. Generally, however, Hahnemann's views contradict those of Brown, though moving somewhat in the same plane. In order to select remedies which should fulfil the indication of producing symptoms like those of the disease, Hahnemann made many observations of the action of drugs on healthy persons. He did not originate this line of research, for it had been pursued if not originated by Haller, and cultivated systematically by Tommasini, an Italian "contra-stimulist;" but he carried it out with much elaboration. His results, nevertheless, were vitiated by being obtained in the interest of a theory, and by singular want of discrimination. Hahnemann's doctrines met with much opposition on the part of the medical profession, and he was hence led to state his case to the "lay" public as a sort of court of appeal; and thus matters of science were made the theme of much popular controversy. This expedient, in which Hahnemann had been in a small degree anticipated by Brown, contributed largely to the success of his system. The appeal flattered a prevalent belief in the right of private judgement, even in technical and learned subjects. Hahnemann was thus able to take up the position (and not without justification) of a victim of professional prejudice. The anomalous position into which professional scorn and extra-professional popularity brought him produced a distinct deterioration in the character of his work. In his second period he developed the extraordinary theory of "potentiality" or dynamization,—namely, that medicines gained in strength by being diluted, if the dilution was accompanied by shaking or pounding, which was supposed to "potentialize" or increase the potency of the medicine. On this extraordinary principle Hahnemann ordered his original tinctures to be reduced in strength to one-fiftieth; these first dilutions again to one-fiftieth; and so on, even till the thirtieth dilution, which he himself used by preference, and to which he ascribed the highest "potentiality." It is hardly necessary to point out that even the lower dilutions involve quantities which no analysis can weigh, measure, or even recognize. The still greater eccentricities of Hahnemann's later works need not be recounted. From a theoretical point of view Hahnemann's is one of the abstract systems, pretending to universality, which modern medicine neither accepts nor finds it worth while to controvert. In the treatment of disease his practical innovations came at a fortunate time, when the excesses of the depletory system had only partially been superseded by the equally injurious opposite extreme of Brown's stimulant treatment. Hahnemann's use of mild and often quite inert remedies contrasted favourably with both of these. Further he did good by insisting upon simplicity in prescribing, when it was the custom to give a number of drugs, often heterogeneous and inconsistent, in the same prescription. But these indirect benefits were quite independent of the truth or falsity of his theoretical system.

*Positive Progress in the 18th Century.*—In looking back on the repeated attempts in the 18th century to construct a universal system of medicine, it is impossible not to

<sup>1</sup> The itch is really an affection produced by the presence in the skin of a species of mite (*Acarus scabiei*), and when this is destroyed or removed the disease is at an end.

regret the waste of brilliant gifts and profound acquirements which they involved. It was fortunate, however, that the accumulation of positive knowledge in medicine did not cease. While Germany and Scotland, as the chief homes of abstract speculation, gave birth to most of the theories, progress in objective science was most marked in other countries,—in Italy first, and afterwards in England and France. We must retrace our steps a little to enumerate several distinguished names which, from the nature of the case, hardly admit of classification.

In Italy the tradition of the great anatomists and physiologists of the 17th century produced a series of accurate observers and practitioners. Among the first of these were Antonio Maria Valsalva (1666–1723), still better known as an anatomist; Giovanni Maria Lancisi (1654–1720), also an anatomist, the author of a classical work on the diseases of the heart and aneurisms; and Ippolito Francesco Albertini (1662–1738), whose researches on the same class of diseases were no less important.

In France Jean Baptiste Sénac (1693–1770) wrote also an important work on the affections of the heart. Sauvages, otherwise F. B. de Lacroix (1706–67), gave under the title *Nosologia Methodica* a natural-history classification of diseases; Jean Astruc (1684–1766) contributed to the knowledge of general diseases. But the state of medicine in that country till the end of the 18th century was unsatisfactory as compared with some other parts of Europe.

In England the brilliancy of the early part of the century in practical medicine was hardly maintained to the end, and presented indeed a certain contrast with the remarkable and unflagging progress of surgery in the same period. The roll of the College of Physicians does not furnish many distinguished names. Among these should be mentioned John Fothergill (1712–80), who investigated the “putrid sore throat” now called diphtheria, and the form of neuralgia popularly known as *tic douloureux*. A physician of Plymouth, John Huxham (1694–1768), made researches on epidemic fevers, in the spirit of Sydenham and Hippocrates, which are of the highest importance. William Heberden (1710–1801), a London physician, called by Samuel Johnson *ultimus Romanorum*, “the last of our learned physicians,” left a rich legacy of practical observations in the *Commentaries* published after his death. More important in their results than any of these works were the discoveries of EDWARD JENNER (*q.v.*), respecting the prevention of small-pox by vaccination, in which he superseded the partially useful but dangerous practice of inoculation, which had been introduced into England in 1721. The history of this discovery need not be told here, but it may be pointed out that, apart from its practical importance, it has had great influence on the scientific study of infectious diseases. The name of John Pringle (1707–82) should also be mentioned as one of the first to study epidemics of fevers occurring in prisons and camps. His work entitled *Observations on the Diseases of an Army* was translated into many European languages, and became the standard authority on the subject.

In Germany the only important school of practical medicine was that of Vienna, as revived by Van Swieten (1700–72), a pupil of Boerhaave, under the patronage of Maria Theresa. Van Swieten's commentaries on the aphorisms of Boerhaave are thought more valuable than the original text. Other eminent names of the same school are Anton de Haen (1704–76), Anton Störck (1731–1803), Maximilian Stoll (1742–88), and John Peter Frank (1745–1821), father of Joseph Frank before-mentioned as an adherent of the Brownian system, and like his son carried away for a time by the new doctrines.

This, the old “Vienna School,” was not distinguished for any notable discoveries, but for success in clinical teaching, and for its sound method of studying the actual facts of disease during life and after death, which largely contributed to the establishment of the “positive medicine” of the 19th century.

One novelty, however, of the first importance is due to a Vienna physician of the period, Leopold Avenbrugger (1722–1809), the inventor of the method of recognizing diseases of the chest by percussion. Avenbrugger's method was that of *direct* percussion with the tips of the fingers, not that which is now used, of *mediate* percussion with the intervention of a finger or plessimeter; but the results of his method were the same, and its value nearly as great. Avenbrugger's great work, the *Inventum Novum*, was published in 1761. The new practice was received at first with contempt and even ridicule, and afterwards by Stoll and Peter Frank with only grudging approval. It did not receive due recognition till 1808, when Corvisart translated the *Inventum Novum* into French, and Avenbrugger's method rapidly attained a European reputation. Surpassed, but not eclipsed, by the still more important art of auscultation introduced by Laennec, it is hardly too much to say that this simple and purely mechanical invention has had more influence on the development of modern medicine than all the “systems” evolved by the most brilliant intellects of the 18th century.

*Early Part of the 19th Century.*—It is not possible to carry the history of medicine, in a sketch such as this, beyond the early years of the 19th century, both because the mass of details becomes so large as to require more minute treatment, and because it is difficult as we approach our own times to preserve the necessary historical perspective. It was, however, in this period that what we regard as the modern school of medicine was formed, and took the shape which it has preserved to our own days. The characteristic of the modern school is the adoption in medicine of the methods of research of physical science, and the gradually declining importance attached to theory and abstract reasoning,—hypotheses, though not neglected, being used as means of research rather than as ultimate conclusions. Its method may therefore be called the positive method, or that of rational empiricism. The growth of the new school was first seen in two European countries, in France and England, and must be separately followed in the two. Germany entered the field later.

*Rise of the Positive School in France.*—The reform of medicine in France must be dated from the great intellectual awakening caused by the Revolution, but more definitely starts with the researches in anatomy and physiology of Marie François Xavier Bichat (1771–1802). The importance in science of Bichat's classical works, especially of the *Anatomie générale*, cannot be estimated here; we can only point out their value as supplying a new basis for pathology or the science of disease. Among the most ardent of his followers was François Joseph Victor Broussais (1772–1838), whose theoretical views, partly founded on those of Brown and partly on the so-called vitalist school of Bordeu and Barthez, differed from these essentially in being avowedly based on anatomical observations. Broussais's chief aim was to find an anatomical basis for all diseases, but he is especially known for his attempt to explain all fevers as a consequence of irritation or inflammation of the intestinal canal (*gastro-entérite*). A number of other maladies, especially general diseases and those commonly regarded as nervous, were attributed to the same cause. It would be impossible now to trace the steps which led to this wild and long since exploded theory. It led, among other consequences, to an enormous misuse of bleeding. Leeches were his favourite

instruments, and so much so that he is said to have used 100,000 in his own hospital wards during one year. He was equalled if not surpassed in this excess by his follower Bouillaud, known for his important work on heart diseases. Broussais's system, to which he gave the name of "*Médecine Physiologique*" did much indirect good, in fixing attention upon morbid changes in the organs, and thus led to the rise of the strongly opposed anatomical and pathological school of Corvisart, Laennec, and Bayle.

Jean Nicolas Corvisart (1755-1821) has already been mentioned as the translator and introducer into France of Avenbrugger's work on percussion. He introduced some improvements in the method, but the only real advance was the introduction of mediate percussion by Piorry in 1828. The discovery had, however, yet to be completed by that of auscultation, or listening to sounds produced in the chest by breathing, the movements of the heart, &c. The combination of these methods constitutes what is now known as *physical diagnosis*. René Théophile Hyacinthe Laennec (1781-1826) was the inventor of this most important perhaps of all methods of medical research. Except for some trifling notices of sounds heard in certain diseases, this method was entirely new. It was definitely expounded in an almost complete form in his work *De l'auscultation médiate*, published in 1819. Laennec attached undue importance to the use of the stethoscope, and laid too much weight on specific signs of specific diseases; otherwise his method in its main features has remained unchanged. The result of his discovery was an entire revolution in the knowledge of diseases of the chest; but it would be a mistake to forget that an essential factor in this revolution was the simultaneous study of the condition of the diseased organs as seen after death. Without the latter, it is difficult to see how the information conveyed by sounds could ever have been verified. This increase of knowledge is therefore due, not to auscultation alone, but to auscultation combined with morbid anatomy. In the case of Laennec himself this qualification takes nothing from his fame, for he studied so minutely the relations of post-mortem appearances to symptoms during life that, had he not discovered auscultation, his researches in morbid anatomy would have made him famous. The pathologico-anatomical method was also followed with great zeal and success by Gaspard Laurent Bayle (1774-1816), whose researches on tubercle, and the changes of the lungs and other organs in consumption, are the foundation of most that has been done since his time. It was of course antecedent to the discovery of auscultation. Starting from these men arose a school of physicians who endeavoured to give to the study of symptoms the same precision as belonged to anatomical observations, and by the combination of both methods made a new era in clinical medicine. Among these were Chomel (1788-1858), Louis (1787-1872), Cruveilhier (1791-1874), and Andral (1797-1876). Louis, by his researches on pulmonary consumption and typhoid fever, had the chief merit of refuting the doctrines of Broussais. In another respect also he aided in establishing an exact science of medicine by the introduction of the numerical or statistical method. By this method only can the fallacies which are attendant on drawing conclusions from isolated cases be avoided; and thus the chief objection which has been made to regarding medicine as an inductive science has been removed. Louis's method was improved and systematized by Gavarret; and its utility is now universally recognized. Space does not permit us to trace further the history of this brilliant period of French medicine, during which the superiority of the school of Paris could hardly be contested. We can only mention the names of Bretonneau (1771-1862), Rostan (1790-1866), D'Alibert (1766-1837), Rayer

(1793-1867), and Trousseau (1801-1866), the eloquent and popular teacher.

*English Medicine from 1800 to 1840.*—The progress of medicine in England during this period displays the same characteristics as at other times, viz., a gradual and uninterrupted development, without startling changes such as are caused by the sudden rise or fall of a new school. Hardly any theoretical system is of English birth; Erasmus Darwin (1731-1802), the grandfather of the great Charles Darwin, alone makes an exception. In his *Zoonomia* (1794) he expounded a theory of life and disease which had some resemblance to that of Brown, though arrived at (he says) by a different chain of reasoning.

Darwin's work shows, however, the tendency to connect medicine with physical science, which was an immediate consequence of the scientific discoveries of the end of the 18th century, when Priestley and Cavendish in England exercised the same influence as Lavoisier in France. The English school of medicine was also profoundly stirred by the teachings of the two brothers William and John Hunter, especially the latter,—who must therefore be briefly mentioned, though their own researches were chiefly concerned with subjects lying a little outside the limits of this sketch. William Hunter (1718-1783) was known in London as a brilliant teacher of anatomy and successful obstetric physician; his younger brother and pupil, John Hunter (1728-1793), was also a teacher of anatomy, and practised as a surgeon. His immense contributions to anatomy and pathology cannot be estimated here, but his services in stimulating research and training investigators belong to the history of general medicine. They are sufficiently evidenced by the fact that Jenner and Baillie were his pupils.

The same scientific bent is seen in the greater attention paid to morbid anatomy (which dates from Baillie), and the more scientific method of studying diseases. An instance of the latter is the work of Robert Willan (1757-1812) on diseases of the skin,—a department of medicine in which abstract and hypothetical views had been especially injurious. Willan, by following the natural-history method of Sydenham, at once put the study on a sound basis; and his work has been the starting point of the most important modern researches. About the same time William Charles Wells (1757-1817), a scientific investigator of remarkable power, and the author of a celebrated essay on dew, published observations on alterations in the urine, which, though little noticed at the time, were of great value as assisting in the important discovery made some years afterwards by Bright.

These observers, and others who cannot be mentioned here, belong to the period when English medicine was still little influenced by the French school. Shortly after 1815, however, when the Continent was again open to English travellers, many English doctors studied in Paris, and the discoveries of their great French contemporaries began to be known. The method of auscultation was soon introduced into this country by pupils of Laennec. John Forbes in 1824, and William Stokes of Dublin in 1825, published treatises on the use of the stethoscope. Forbes also translated the works of Laennec and Avenbrugger, and an entire revolution was soon effected in the knowledge of diseases of the chest. James Hope and Peter Mere Latham further developed this subject, and the former was also known for his researches in morbid anatomy. The combination of clinical and anatomical research led, as in the hands of the great French physicians, to important discoveries by English investigators. The discovery by Richard Bright (1789-1858) of the disease of the kidneys known by his name, has proved to be one of the most momentous of this century. It was published in *Reports of*

*Medical Cases*, 1827-31. Thomas Addison takes, somewhat later, a scarcely inferior place. The remarkable physiological discoveries of Bell and Marshall Hall for the first time rendered possible the discrimination of diseases of the spinal cord. Several of these physicians were also eminent for their clinical teaching,—an art in which Englishmen had up till then been greatly deficient.

Although many names of scarcely less note might be mentioned among the London physicians of the early part of the century, we must pass them over to consider the progress of medicine in Scotland and Ireland. In Edinburgh the admirable teaching of Cullen had raised the medical faculty to a height of prosperity of which his successor, James Gregory (1758-1821), was not unworthy. His nephew, William Pulteney Alison (1790-1859), was even more widely known. These great teachers maintained in the northern university a continuous tradition of successful teaching, which the difference in academical and other circumstances rendered hardly possible in London. Nor was the northern school wanting in special investigators, such as John Abercrombie, known for his work on diseases of the brain and spinal cord published in 1828, and many others. Turning to Ireland, it should be said that the Dublin school in this period produced two physicians of the highest distinction. Robert James Graves (c. 1800-1853) was a most eminent clinical teacher and observer, whose lectures are regarded as the model of clinical teaching, and indeed served as such to the most popular teacher of the Paris school in the middle of this century, Trousseau. William Stokes (1804-1878) was especially known for his works on diseases of the chest and of the heart, and for his clinical teaching.

*German Medicine from 1800 to 1840.*—Of the other countries of Europe, it is now only necessary to mention Germany. Here the chief home of positive medicine was still for a long time Vienna, where the "new Vienna school" continued and surpassed the glory of the old. Joseph Skoda (born 1805) extended, and in some respects corrected, the art of auscultation as left by Laennec. Karl Rokitsky (1804-1878), by his colossal labours, placed the science of morbid anatomy on a permanent basis, and enriched it by numerous discoveries of detail. Most of the ardent cultivators of this science in Germany in the next generation were his pupils. In the other German schools, though some great names might be found, as Romberg (1795-1873), the founder of the modern era in the study of nervous diseases, the general spirit was scholastic and the result barren, till the teaching of one man, whom the modern German physicians generally regard as the regenerator of scientific medicine in their country, made itself felt. Johann Lucas Schönlein (1793-1864) was first professor at Würzburg, afterwards at Zurich, and for

twenty years at Berlin (from 1839-1859). Schönlein's positive contributions to medical science were not large; but he made in 1839 one discovery, apparently small, but in reality most suggestive, namely, that the contagious disease of the head called favus is produced by the growth in the hair of a parasitic fungus. In this may be found the germ of the startling modern discoveries in parasitic diseases. His systematic doctrines founded the so-called "natural history school;" but his real merit was that of the founder or introducer of a method. In the words of Haeser, "Schönlein has the incontestable merit of having been the first to establish in Germany the exact method of the French and the English, and to impregnate this method with the vivifying spirit of German research." The name of Schönlein thus brings us to the threshold of the modern German school of medicine,—the most scientific and exact in Europe, and in its spirit strikingly in contrast with the theoretical subtlety of German systematists in the last century.

*Literature.*—The earliest work of authority on the history of medicine is that of Daniel le Clerc (*Histoire de la Médecine*, Geneva, 1696; Amsterdam, 1704, 1723, &c.), which ends with Galen. Fröind's *History of Physick* (London, 1725-26, 2 vols.) carries on the subject from Galen to the beginning of the 16th century. The first complete history is that of Kurt Sprengel (*Versuch einer pragmatischen Geschichte der Arzneikunde*, Halle, 1792; 3d edition, Halle, 1821-23, 5 vols.; also in French, Paris, 1815). Beside these may be mentioned Hecker, *Geschichte der Heilkunde*, Berlin, 1822, and *Gesch. der neueren Heilkunde*, Berlin, 1839; Ch. Daremberg, *Histoire des sciences médicales*, Paris, 1870, 2 vols.; Edward Meryon, *History of Medicine*, London, 1861 (left unfinished, vol. i. only having appeared). The most recent and complete text-book is Haeser's *Lehrbuch der Geschichte der Medizin und der Epidemischen Krankheiten* (3d edition, Jena, 1875-79, 8 vols., in course of completion), to which the preceding sketch is very largely indebted.

In special departments of the subject the authorities are the following:—For classical medicine: Celsus, *De Medicina*; Littre, *Œuvres d'Hippocrate*, Paris, 1839-61, 10 vols. (especially vol. i.); Francis Adams, *Genuine Works of Hippocrates translated, with a Preliminary Discourse*, London (Syd. Soc.), 1849, and *Paulus Ægineta, translated, with a Commentary*, London (Syd. Soc.), 1844; Daremberg, *La Médecine dans Homère*, Paris, 1865, and *La Médecine entre Homère et Hippocrate*, Paris, 1869; and W. A. Greenhill's articles "Galen," "Hippocrates," &c., in *Smith's Classical Dictionary*, 1844. For Arabian medicine: Wüstenfeld, *Geschichte der Arabischen Aerzte und Naturforscher*, Göttingen, 1840; and Lucien Leclerc, *Histoire de la Médecine Arabe*, Paris, 1876, 2 vols. For Salernitan medicine: *Collectio Salernitana*, edited by De Renzi, Daremberg, &c., Naples, 1852, 5 vols.; *Regimen Sanitatis*, with introduction by Sir A. Croke, Oxford, 1830; and Daremberg, *L'École de Salerne*, Paris, 1861. For medicine in England: John Aikin, *Biographical Memoirs of Medicine in Great Britain, to the time of Harvey*, London, 1780; *Lives of British Physicians*, London, 1830 (chiefly by Dr Macmichael, partly by Dr Bisset Hawkins and Dr H. H. Southey); and Munk, *Roll of the Royal College of Physicians of London*, 2d ed., 1878, 3 vols. For the modern schools: Hirschel, *Geschichte des Brown'schen Systems und der Erregungs Theorie*, Leipsic, 1846; Bouchut, *Histoire de la Médecine et des Doctrines Médicales*, 2 vols., Paris, 1873 (comparison of ancient and modern schools); Buckle, *History of Civilization in England*, 1858-61. (J. F. P.)

MEDINA, or rather EL-MEDÍNA (the city), or MEDÍNAT RASÚL ALLÁH (the city of the apostle of God), a town of the Hijáz in Arabia, in 25° N. lat., 40 E. long.<sup>1</sup> the refuge of Mohammed on his flight from Mecca, and a renowned place of Moslem pilgrimage, consecrated by the possession of his tomb. The name El-Medína goes back to the Koran (*sur.* xxxiii. 60); the old name was Yathrib, the Lathrippa of Ptolemy and Iathrippa of Stephanus Byzantius.

<sup>1</sup> This can only be viewed as a very rough estimate. The road from Yanbu' on the Red Sea, which runs somewhat north of east, is by Burton's estimate 132 miles. From Medina to Mecca by the inland or high road he makes 248 miles. The usual road near the coast by Rábig and Kholeys and thence to W. Fátima cannot be very different in length. Caravans traverse it in about ten or eleven days.

Medina stands in a sort of basin at the northern extremity of an elevated plain, on the western skirt of the mountain range which divides the Red Sea coast-lands from the central plateau of Arabia. At an hour's distance to the north it is dominated by Mount Ohod, an outlying spur of the great mountains, which is now visited by the pious as the scene of the well-known battle (see MOHAMMED), and the site of the tomb and mosque of the Prophet's uncle Hamza. To the east the plain is bounded by a long line of hills eight or ten hours distant, over which the Nejd road runs. A number of torrent courses (of which W. Kanát to the north, at the foot of Mount Ohod, and W. Akik, some miles to the south, are the most important) descend from the mountains, forming considerable streams and pools after rain, and converge in the

neighbourhood of the town to unite farther west at a place called Zaghába, whence they descend to the sea through the "mountains of the Tiháma"—the rough country between Medina and its port of Yanbu—under the name of W. Idam. Southwards from Medina the plain extends unbroken, but with a slight rise, as far as the eye can reach. The convergence of torrent courses in the neighbourhood of Medina makes this one of the best-watered spots in northern Arabia. The city lies close to one of the great volcanic centres of the peninsula, which was in violent eruption as late as 1266 A.D., when the lava stream approached within an hour's distance of the walls, and dammed up W. Kanát. The result of this and older prehistoric eruptions has been to confine the underground water, so important in Arabian tillage, which can be reached at any point of the oasis by sinking deep wells. Many of the wells are brackish, and the natural fertility of the volcanic soil is in many places impaired by the salt with which it is impregnated; but the date palm grows well everywhere, and the groves, interspersed with gardens and corn-fields, which surround the city on all sides except the west, have been famous from the time of the Prophet. Thus situated, Medina was originally a city of agriculturists, not like Mecca a city of merchants; nor, apart from the indispensable trade in provisions, has it ever acquired commercial importance like that which Mecca owes to the pilgrimage.<sup>1</sup> Landowners and cultivators are still a chief element in the population of the city and suburbs. The latter, who are called Nawákhila, and more or less openly profess the Shí'a opinions, form a sort of separate caste, marrying only among themselves. The townsmen proper, on the other hand, are a very motley race.<sup>2</sup> The mechanical arts, which the true Arab despises, are chiefly practised by foreigners. New settlers remain behind with each pilgrimage; and the many offices of profit connected with the mosque, the stipends paid by the sultan to every inhabitant, and the gains to be derived by pilgrim-cicerones (Muzawwirs) or by those who make it a business to say prayers at the Prophet's mosque for persons who send a fee from a distance, as well as the alms which the citizens are accustomed to collect when they go abroad, especially in Turkey, keep up an idle population greatly in excess of that which the district would naturally support in the present defective state of agriculture. The population of the city and suburbs may be from 16,000 to 20,000 souls.

The city proper is surrounded by a solid stone wall,<sup>3</sup> with towers and four massive gateways of good architecture, forming an irregular oval running to a kind of angle at the north-west, where stands the castle, held by a Turkish garrison. The houses are good stone buildings similar in style to those of Mecca; the streets are narrow but clean, and in part paved.<sup>4</sup> There is a copious supply of water conducted from a tepid source at the village of Kubá, 2 miles south, and distributed in underground cisterns in each quarter.<sup>5</sup> The glory of Medina, and the only im-

portant building, is the mosque of the Prophet, in the eastern part of the city, a spacious enclosed court between 400 and 500 feet in length from north to south, and two-thirds as much in breadth. The minarets and the lofty dome above the sacred graves are imposing features, but the circuit is hemmed in by houses or narrow lanes, and is not remarkable except for the principal gate (Báb el-Salám) at the southern end of the west front, facing the sacred graves, which is richly inlaid with marbles and fine tiles, and adorned with golden inscriptions. This gate leads into a deep portico, with ten rows of pillars, running along the southern wall. Near the further end of the portico, but not adjoining the walls, is a sort of doorless house or chamber hung with rich curtains, which is supposed to contain the graves of Mohammed, Abubekr, and 'Omar. To the north of this is a smaller chamber of the same kind, draped in black, which is said to represent the house or tomb of Fátima. Both are enclosed within an iron railing, so closely interwoven with brass wire-work that a glimpse of the so-called tombs can only be got through certain apertures where intercessory prayer is addressed to the prophet, and pious salutations are paid to the other saints.<sup>6</sup> The portico in front of the railing is not ineffective, at least by night light. It is paved with marble, and in the eastern part with mosaic, laid with rich carpets; the southern wall is clothed with marble pierced with windows of good stained glass, and the great railing has a striking aspect; but an air of tawdriness is imparted by the vulgar painting of the columns, especially in the space between the tomb and the pulpit, which has received, in accordance with a tradition of the Prophet, the name of the Garden (rawdá), and is decorated with barbaric attempts to carry out this idea in colour.<sup>7</sup> The throng of visitors passing along the south wall from the Báb el-Salám to salute the tombs is separated from the Garden by a wooden partition about 8 feet high, painted in arabesques. The other three sides of the interior court have porticos of less depth and mean aspect, with three or four rows of pillars. Within the court are the well of the Prophet and some palm trees said to have been planted by Fátima.

The original mosque was a low building of brick roofed with palm branches, and much smaller than the present structure. The wooden pulpit from which Mohammed preached appears to have stood on the same place with the present pulpit in the middle of the south portico. The dwelling of the Prophet and the huts of his women adjoined the mosque. Mohammed died in the hut of 'Áisha, and was buried where he died; Abubekr and 'Omar were afterwards buried beside him. Now in 711 A.D. the mosque, which had previously been enlarged by 'Omar and 'Othmán, was entirely reconstructed on a grander scale and in Byzantine style by Greek and Coptic artificers at the command of the caliph Walíd and under the direction of 'Omar ibn 'Abd el-'Azíz. The enlarged plan included the huts above named, which were pulled down. Thus the place of the Prophet's burial was brought within the mosque; but the recorded discontent of the city at this step shows that the feeling which regards the tomb as the great glory of the mosque, and the pilgrimage to it as the most meritorious that can be undertaken except that to Mecca, was still quite unknown. It is not even certain

entered Medina, and the site of the first mosque in which he prayed. It lies amidst orchards in the richest part of the oasis.

<sup>6</sup> The space between the railing and the tomb is seldom entered except by the servants of the mosque. It contains the treasures of the mosque in jewels and plate, which were once very considerable but have been repeatedly plundered, last of all by the Wahhábis in the beginning of the present century.

<sup>7</sup> The word *rawdá* also means a mausoleum, and is applied by Ibn Jubair to the tomb itself. Thus the tradition that the space between the pulpit and tomb was called by the Prophet one of the gardens of Paradise probably arose from a mistake.

<sup>1</sup> The pilgrimage to Medina, though highly meritorious, is not obligatory, and it is not tied to a single season, so that there is no great concourse at one time, and no fair like that of Mecca.

<sup>2</sup> A small number of families in Mecca still claim to represent the ancient Anşár, the "defenders" of Mohammed. But in fact the old population emigrated *en masse* after the sack of Medina by Muslim in 688, and passed into Spain in the armies of Músá. In the 13th century one old man of the Khazraj and one old woman of the Aus tribe were all that remained of the old stock in Medina (Makkari, i. 187; Dozy, *Mus. d'Espagne*, i. 111). The aristocratic family of the Bení Huseyn, who claim descent from the martyr of Kerbela, and so from the Prophet, have apparently a better established pedigree.

<sup>3</sup> According to Ibn Khallikán (Slane's transl., iii. 927) the walls are of the 12th century, the work of Jamál el-Dín el-Ispahání.

<sup>4</sup> The Balát or great paved street of Medina, a very unusual feature in an Eastern town, dates from the 1st century of Islám. See Wüstenfeld's abstract of Samhúdí, p. 115.

<sup>5</sup> Kubá is famous as the place where the prophet lived before he

what was done at this time to mark off the graves. Ibn 'Abd Rabbih, in the beginning of the 10th century (*Ikd*, Cairo ed., iii. 366), describes the enclosure as a hexagonal wall, rising within three cubits of the ceiling of the portico, clothed in marble for more than a man's height, and above that height daubed with the unguent called khalūk. This may be supplemented from Istakhrī, who calls it a lofty house without a door. That there are no gravestones or visible tombs within is certain from what is recorded of occasions when the place was opened up for repairs. Ibn Jubair (p. 193 sq.) and Samhūdī speak of a small casket adorned with silver, fixed in the eastern wall, which was supposed to be opposite the head of the Prophet, while a silver nail in the south wall indicated the point to which the corpse faced, and from which the salutation of worshippers was to be addressed (Burton misquotes). The European fable of the coffin suspended by magnets is totally unknown to Moslem tradition. The smaller chamber of Fátima is pretty modern. In the time of Ibn Jubair and of Ibn Batūta (unless the latter, as is so often the case, is merely copying his predecessor) there was only a small marble trough north of the rauda (or grave) which "is said to be the house of Fátima or her grave, but God only knows." It is more probable that Fátima was buried in the Bakī, where her tomb was also shown in the 12th century (Ibn Jubair, p. 198 sq.).

The mosque was again extended by El-Mahdī (781 A.D.), and was burned down in 1256. Of its appearance before the fire we have two authentic accounts by Ibn 'Abd Rabbih early in the 10th century, and by Ibn Jubair, who visited it in 1184. The old mosque had a much finer and more regular appearance than the present one; the interior walls were richly adorned with marble and mosaic arabesques of trees and the like, and the outer walls with stone marquetry; the pillars of the south portico (seventeen in each row) were in white plaster with gilt capitals, the other pillars were of marble. Ibn 'Abd Rabbih speaks of eighteen gates, of which in Ibn Jubair's time, as at present, all but four were walled up. There were then three minarets. After the fire which took place just at the time of the fall of the caliphate, the mosque long lay in a miserable condition. Its repair was chiefly due to the Egyptian sultans, especially to Kāit Bey, whose restoration after a second fire in 1481 amounted almost to a complete reconstruction. Of the old building nothing seems to have remained but some of the columns and part of the walls; and, as the minarets have also been rebuilt and two new ones added, the architectural character is now essentially Egyptian. The great dome above the tomb, the railing round it, and the pulpit, all date from Kāit Bey's restoration.

The suburbs, which occupy as much space as the city proper, and are partly walled in, lie south-west of the town, from which they are separated by an open space, the halting-place of caravans. Through the suburbs runs the watercourse called W. Buṭḥān, a tributary of W. Kanāt, which the Yanbū road crosses by a stone bridge. The suburbs are the quarter of the peasants. Thirty or forty families with their cattle occupy a single courtyard (ḥōsh), and form a kind of community often at feud with its neighbours. The several clans of Medina must have lived in much the same way at the time of the Prophet. The famous cemetery called Bakī el-Gharkad, the resting-place of a multitude of the "companions" of the Prophet, lies immediately to the west of the city. It once contained many monuments, the chief of which are described by Ibn Jubair. Burckhardt in 1815 found it a mere waste, but some of the mosques have since been rebuilt.

*History.*—The story of the Amalekites in Yathrib and of their conquest by the Hebrews in the time of Moses is purely fabulous,

see Noldeke, *Ueber die Amalekiter*, 1864, p. 36. The oasis, when it first comes into the light of history, was held by Jews, among whom emigrants from Yemen afterwards settled. From the time of the flight of Mohammed (622 A.D.) till the Omayyads removed the seat of empire from Medina to Damascus, the town springs into historic prominence as the capital of the new power that so rapidly changed the fate of the East. Its fall was not less rapid and complete, and since the battle of Harra and the sack of the city in 683 it has never regained political importance. The history of Medina in this period will be told in the articles MOHAMMED and MOHAMMEDAN EMPIRE. Mohammed invested the country round Medina with an inviolable character like that of the Haram round Mecca; but this provision has never been observed with strictness. After the fall of the caliphs, who maintained a governor in Medina, the native emirs enjoyed a fluctuating measure of independence, interrupted by the aggressions of the sheriffs of Mecca, or controlled by an intermittent Egyptian protectorate. The Turks after the conquest of Egypt held Medina for a time with a firmer hand; but their rule grew weak, and was almost nominal long before the Wahhābīs took the city in 1804. A Turko-Egyptian force retook it in 1812, and the Turks still maintain a pasha with a military establishment, while the cadi and chief agha of the mosque (a eunuch) are sent from Constantinople. But the internal government is largely in Arab hands, and is said to be much better than that of Mecca.

*Sources.*—Medina has been described from personal observation by Burckhardt, who visited it in 1815, and Burton, who made the pilgrimage in 1863. Sadlier on his journey from Kaṭīf to Yanbū (1819) was not allowed to enter the holy city. Burckhardt was prevented by ill health from examining the city and country with his usual thoroughness. Little is added to our information by the report of 'Abd el-Razzāk, who performed the pilgrimage in 1873, on a medical commission from the English Government. The chief Arabic authority besides Ibn 'Abd Rabbih and Ibn Jubair is Samhūdī, of whose history Wüstenfeld published an abstract in the *Göttingen Abhandlungen*, vol. ix., 1861. It goes down to the end of the 15th century. The topography of the country about Medina is interesting both historically and geographically; Bekrī, Yāqūt, and other Arabic geographers supply much material on this topic, but complete European accounts are wanting to permit of its full utilization. Medina now offers a more promising, but also a more perilous, field for an explorer than Mecca. (W. P. S.)

**MEDINA SIDONIA**, a town of Spain, in the province of Cadiz, and about 21 miles by road westward from that city, stands at a height of 600 feet above the sea-level, on an isolated hill surrounded by a cultivated plain. Apart from its picturesque airy situation it has nothing to interest the traveller; the streets are narrow, steep, and dirty, and its buildings and ruins are unimportant. The occupations of the inhabitants are connected chiefly with the agriculture and cattle-breeding carried on in the surrounding district; bricks and pottery are also made to some extent. The population in 1877 was 12,234.

Medina Sidonia has been identified by some with the *Asido* of Pliny, but it is uncertain whether Jerez is not more probably the locality referred to by that name. Under the Visigoths the place was erected into a bishopric (Assidonia), and attained some importance; in the beginning of the 8th century it was taken by Tarik. In the time of Edrisi the province of Shadūna or Shidona included, among other towns, Seville and Carmona; later Arab geographers place Shadūna in the province of Seville. The town gives its title to the ducal house of Guzman el Bueno, the hero of Tarifa (1292).

**MEDITERRANEAN SEA.** The southern shores of Europe are separated from the northern shores of Africa by the Mediterranean Sea. It extends in a generally east and west direction from longitude 5° 21' W. to 36° 10' E. Its length from Gibraltar to its eastern extremity in Syria is about 2100 miles. Its breadth is very various, being 400 miles from the mouth of the Rhone to the Algerian coast, 500 miles from the Gulf of Sidra to the entrance to the Adriatic, and 250 miles from the mouth of the Nile to the south coast of Asia Minor. From the very indented nature of its coasts, the general mass of the water is much cut up into separate seas, which have long borne distinctive names, as the Adriatic, the *Ægean*, the Sea of Marmora, the Black Sea, &c. The area of the whole system, including the Sea of Azoff, is given by Admiral Smythe as 1,149,287 square miles. If we deduct that of the Black Sea and Sea of Azoff, 172,506 square miles, we have for the area of the Mediterranean proper 976,781, or, roughly speaking, a million of square miles.

The Mediterranean is sharply divided into two great principal basins, the western and the eastern or Levant

basin. The western possesses a comparatively smooth and unindented coast-line. It is bounded on the south by the coast of Africa and the north coast of Sicily, and it is further enclosed by the coasts of Spain, France, and Italy, which form a roughly arc-shaped coast-line. There are comparatively few small islands in this basin, though some of the more important large ones occur in it. The eastern basin is by far the larger of the two, and extends from Cape Bon to the Syrian coast, including as important branches the Adriatic and the *Ægean*. The latter is connected directly, through the Hellespont, the Sea of Marmora, and the Bosphorus, with the Black Sea. The entrance to the western basin and to the sea generally from the ocean is through the Straits of Gibraltar in  $36^{\circ}$  N. lat. If this parallel be drawn out through the sea it will be found that the western basin lies almost wholly to the northward, and the main body of the eastern one to the southward of it, the mean latitude of the western basin being about  $39^{\circ} 30'$ , and that of the eastern basin  $35^{\circ}$ . They communicate with each other by the channels separating Sicily from Italy and from Africa. The former is known as the Strait of Messina, and is of insignificant size, the latter is a wide channel apparently without any distinctive name, and generally shallow. The greatest depth on the shallowest ridge reaching from the African to the Sicilian coast is under 200 fathoms, and agrees very closely with the corresponding depth at the entrance to the Straits of Gibraltar.

*Depth.*—So far as is at present known, the maximum depth is pretty nearly alike in the two basins, being 2040 fathom in the western and 2150 fathoms in the eastern. Many lines of soundings have been run in the Mediterranean for telegraph purposes, and they afford a very good idea of the general configuration of the bottom. Between Marseilles and Algiers the depth ranges generally from 1200 to 1600 fathoms; between Naples and Sardinia from 1500 to 2000; between Alexandria and Rhodes from 1200 to 1600; and between Alexandria and Cyprus from 900 to 1100. The basin of the Mediterranean really begins about 50 miles to the westward of Gibraltar. It is here that the shallowest ridge stretches across from Africa to Spain; the maximum depth on it is probably not more than 180, and certainly less than 200 fathoms. From this ridge the bottom slopes quickly westward into the depths of the Atlantic, and gently eastward into the Mediterranean. The depth nowhere reaches 1000 fathoms until beyond Alboran Island, 120 miles east of Gibraltar. This is a small low island separated from the mainland on all sides by water of more than 400 fathoms; it must therefore be considered an oceanic as distinguished from a continental island.<sup>1</sup> Further to the north, and off the coast of Valencia, we have the Balearic Islands,—namely, Majorca, Minorca, Iviza, and Formentera. These also must be considered oceanic islands, and indeed two groups of oceanic islands. Iviza and Formentera are isolated both from the Spanish coast and from the other two islands by water of over 300 fathoms depth; Majorca and Minorca are connected by a bank with no more than 50 fathoms of water on it. Thirty miles east of Minorca there are more than 1400 fathoms; beyond that there are no soundings between the Balears and the large and important group of Corsica and Sardinia. These islands are continental, being connected with the Italian mainland by the bank on which Elba occurs, and which is covered by little over 50 fathoms of water. The Straits of Bonifacio, which separate Corsica from Sardinia, are also quite shallow, so that Corsica and Sardinia may be looked on as a secondary peninsula attached to the Tuscan

shore of Italy by a shallow bank not more than 15 or 20 miles broad, the deep water coming close up all round it. Almost the same may be said of Sicily, including the Malta group, but excluding the Lipari group, which is purely volcanic. From Cape Passaro, in the south-east end of Sicily, a line can be drawn connecting it with the town of Tripoli, and without passing over water of more than 300 fathoms. As has already been said, the west end of Sicily is connected with the coast of Tunis by a ridge in no part covered by more than 200 fathoms of water. Between these two ridges lies a small but comparatively deep basin of 600 to 700 fathoms. At the western extremity of it lies the mountainous island of Pantellaria. The bank on which Malta is situated stretches for nearly 100 miles in a southerly direction from Cape Passaro in Sicily. Opposite, on the African shore, is a similar bank of much larger dimensions, on which are the small islands Lampion and Lampedusa belonging to Italy. In the deep channel between them and Malta is the small but lofty island Limosa. It is entirely volcanic, with an extinct crater on its north-eastern side, and three smaller ones to the southward. It resembles the Lipari group off the north coast of Sicily, which rise abruptly out of deep water, being connected by no bank either with the African or the Sicilian coasts. Some of the Lipari group are still active, Stromboli and Vulcano being of the number. Off the south coast of Sicily, and between it and the island of Pantellaria, occurs the famous Graham's shoal, the remains of what was for a few weeks an island.<sup>2</sup>

The deepest water of the Mediterranean is found in its widest part between Malta and Crete, and the deep water comes close up to the Italian and Greek coasts, while on the African shore the water shoals more gradually. In the Strait of Messina, close to Reggio, there are depths of over 500 fathoms, and similar depths are found inside gulfs such as those of Taranto (nearly 1000 fathoms), of Corinth, Kalamata, and others. Also all through the *Ægean* in its many bights and channels very deep water is met with; in the Sea of Marmora we have 500 fathoms, and in the Black Sea over 1000 fathoms. All along the south coast of Asia Minor the water is very deep, and the large islands of Cyprus and Crete are both separated by very deep water from the mainland. If we take the eastern basin, and run along its western and southern coasts from the mouth of the Po along the shore of Italy, Sicily, and Africa to the mouth of the Nile, and even further along the Syrian shore, we do not find a single off-lying island of any importance except the Malta group, while all along the eastern and northern coasts from Trieste to Asia Minor the coast is deeply indented, and the water broken up by many large and important islands. These islands are grouped along the west coast of Turkey and Greece, and irregularly throughout the *Ægean*. The east coast of the Adriatic is studded with islands and inlets, and resembles in this respect the *Ægean*; the west coast, on the other hand, is low, and the water off it shallow, and there are few harbours. The Adriatic stretches in a north-westerly direction for about 460 miles from its entrance between

<sup>1</sup> Continental islands are those separated from the mainland by comparatively shallow seas, generally under 100 fathoms.

<sup>2</sup> With regard to its appearance and disappearance Admiral Smythe (*Mediterranean*, p. 111) says:—"It seems that, as early as the 28th of June 1831, Captain Swinburne, in passing nearly over the spot, felt several shocks of a sea-quake, proving that the cause was then in operation; but on the 19th of the following July the crater had accumulated to a few feet above the level of the sea, and was in great activity, emitting vast volumes of steam, ashes, and scorise. From that time it gradually increased in all its dimensions till towards the end of August its circumference was about 3240 feet and its height 107; then from October various changes took place, and it entirely disappeared in December." Since that time it has changed considerably. In 1863 the least water on it was 15 feet. It has two heads close together, and at the distance of about 20 yards all round there are from 7 to 9 fathoms of water.

Cape Sta Maria di Leuca and the island of Corfu to the Venetian shore in the Gulf of Trieste. Its average width is about 100 miles. A ridge with little over 400 fathoms appears to run across its entrance. Inside this the water reaches a depth of 765 fathoms, but shoals again rapidly towards Pelagosa Island, from which to the northward, including quite two-thirds of the sea, the depth is under 100 fathoms; indeed no part of the sea within 150 miles of its northern extremity is over 50 fathoms deep. There is authentic historical evidence of the encroachment of the Italian shores on the Adriatic, causing thereby a diminution of its area. As a consequence many towns which were once thriving seaports are now many miles inland; thus Adria, which was a station of the Roman fleet, is now 15 miles inland, and there are many similar examples. The large rivers Po and Adige, which bring the drainage of the southern slopes of the Alps to the sea, deliver large quantities of sediment in the course of the year. The distribution of this mud is affected, not only by its own weight tending to make it sink to the bottom, but also by the set of the currents, which, running up the eastern coast, turn to the westward and southward at the upper end of the sea, and so tend to distribute the river mud along the bottom in the neighbourhood of the Italian coasts. The fact that towns which were formerly seaports are now inland does not therefore necessitate the assumption of a general rise of the land, it is merely a reclamation by natural agencies of land from the sea at the expense of the inland mountainous country. Precisely similar phenomena are observed in the neighbourhood of the mouths of the Rhone and of the Nile.

*Specific Gravity, Currents, &c.*—On the specific gravity Dr Carpenter reports many and interesting observations. In round numbers, that of the surface-water of the Atlantic off the Straits of Gibraltar is 1·0260 to 1·0270, that of the western basin of the Mediterranean 1·0280 to 1·0290, and that of the eastern basin 1·0290 to 1·0300, while that of the Black Sea is 1·0120 to 1·0140. It will thus be seen that the water of the Mediterranean proper is very much saltier than either the Atlantic on the west or the Black Sea on the east, and this great density of the water affords a useful means of recognizing it when investigating the interchange of waters which takes place at the two extremities of the sea. Both the temperature and the specific gravity of the water are evidences of the local climate. The great concentration of the water shows how dry the atmosphere at the surface must be, and how insignificant the contributions of fresh water. With regard to the balance existing between the two factors, evaporation and precipitation, it would be impossible to give figures with any claim to accuracy, but a rough estimate may be formed by taking such data as Fischer has given. He puts the rainfall over the whole Mediterranean drainage area at 759·4 millimetres, or almost exactly 30 inches. If we remember that the average rainfall of the eastern slopes of Great Britain is less than 30 inches, and that therefore this may be taken as the maximum yearly supply to the North Sea, we may be sure that the Mediterranean does not receive more than 30 inches of fresh water in the year. With regard to the rate of evaporation over the area of the Mediterranean there is but very meagre information, but wherever it has been observed it has been found to exceed the rainfall, even as much as three times. Thus at Madrid it is 65 inches, or more than four times the rainfall, at Rome 105 inches, and at Cairo 92 inches. It may therefore without exaggeration be assumed that the evaporation is at least twice as great as the precipitation. Putting the latter at 30 inches, we should have 60 inches for the yearly evaporation, and a balance of 30 inches evaporation over precipitation. Were there no provision for making good this deficiency, the

level of the Mediterranean would sink until its surface was so far contracted as to lose no more by evaporation than would be supplied by rain. This condition would probably not be fulfilled before all the Ægean and Adriatic and the whole of the western basin west of the island of Sardinia were laid dry, and what is now the Mediterranean would be reduced to two "Dead Seas," one between Sardinia and Naples and the other between Africa and the mouth of the Adriatic. That the level and the salinity of the Mediterranean remain constant is due to the supply of water which enters at the Straits of Gibraltar. The currents in this passage have frequently engaged attention both from their scientific and their nautical interest. The most detailed investigation was that carried out by Captain Nares and Dr Carpenter in H.M.S. "Shearwater" in the year 1871.<sup>1</sup> From these investigations it appears that there are usually two currents in the Straits at the same time, one superposed on the other. Both are affected by tidal influence, but, after allowing for it, there is still a balance of inflow in the upper and of outflow in the under current. The waters of the two currents are sharply distinguished from each other by their salinity. Further, the upper current appears to affect by preference the middle of the channel and the African coast, while the under current appears to crop out at the surface on the Spanish coast. This distribution, however, is much modified by the state of the tide, and it must be remembered that in such places the surface separating the upper and under currents is rarely, if ever, a horizontal plane. That there is a balance of outflow over inflow at the bottom was well shown by the result of soundings as much as 200 miles north-west of the entrance of the Straits, where, in a depth of 1560 fathoms, water of decided Mediterranean origin was got from the bottom. There can be no doubt that this outflow of warm and dense Mediterranean water is largely instrumental in causing the comparatively very high bottom temperature in the eastern basin of the North Atlantic.

We have assumed that the balance of water removed by evaporation is 30 inches, or 2·5 feet. If we take the area of the Mediterranean to be 1,000,000 square miles, we have the volume of water removed—

$$v = 2.5 \times 36 \times 10^{12} = 90 \times 10^{12} \text{ cubic feet.}$$

This quantity of water has to be supplied from the Atlantic without raising the total quantity of salt in the sea. We have seen that the only provision for the removal of the surplus salt is the outward under current in the Straits. Hence the inward upper current must be sufficient to replace the water lost both by evaporation and by the outflow of the under current. We may take the Atlantic water to contain 3·6 per cent. and the Mediterranean to contain 3·9 per cent. of salt. In order that the under current may remove exactly as much salt as is brought in by the upper one, their volumes must be in the inverse ratio of their saline contents, or the volume of the upper current must be to that of the under one in the ratio 39 : 36 or 1000 : 923; so that only 7·7 per cent. of the inflow goes to replace the water removed by evaporation, while the remaining 92·3 per cent. replaces the water of the under current. We have then for the total volume of the inward current per annum

$$V = \frac{100}{7.7} v = 1170 \times 10^{12} \text{ cubic feet.}$$

The width of the Straits from Tarifa to Point Cires is 8 miles, or 48,000 feet, and the average depth of the stream may fairly be taken as 100 fathoms; hence the sectional area is in round numbers 29,000,000 square feet.

<sup>1</sup> *Proc. Roy. Soc.* (1872), xx. 97, 414.

Dividing the volume by the area we have for the mean annual flow

$$R = \frac{1170 \times 10^{12}}{29 \times 10^6} = 40 \times 10^6 \text{ feet.}$$

Reducing this to miles per day, we find that if the above data are correct the inflowing current at the Straits of Gibraltar ought to be equivalent to a current 8 miles wide, 100 fathoms deep, and running with the uniform velocity of 18.3 miles in twenty-four hours. As the currents are reversed with the tides this is the balance of inflow over outflow in the upper current. It is worthy of remark that the flood tide runs to the westward at the surface and the ebb to the eastward. The following table of tides at places inside and outside the Straits will show that the mere differences of level due to the different tidal ranges at adjacent localities are sufficient to cause strong local currents.

A similar phenomenon is witnessed at the other end of the sea. Here the fresher waters of the Black Sea rush in through the narrow channel of the Dardanelles, causing a surface inflow of comparatively fresh water, while there is an outflow below of denser Mediterranean water. The dimensions of the Straits are too small to make the phenomenon of any importance for the supply of the Mediterranean. The conditions both in the Dardanelles and in the Bosphorus were examined very carefully in the year 1872 by Captain Wharton, R.N., of H.M.S. "Shearwater," and his results are published in an interesting report to the admiralty, of that date. It is remarkable that the comparatively fresh water of the Black Sea persists without sensible mixture through the Sea of Marmora and into the Dardanelles, while there is constantly a current of Mediterranean water running underneath, and the depth in the two channels is only from 30 to 50 fathoms. There can be little doubt that the saltness of the Black Sea is due wholly to the return current of Mediterranean water entering through the Bosphorus. Were the exit of the Black Sea a channel with sufficient fall to bring the surface of the Sea of Marmora below the level of the highest part of its bottom, so that no return current could take place, the waters of the Black Sea would be fresh.

In the body of the sea the rise and fall are much less than at any of the places in the above table. At Algiers a self-recording tide gauge was set up by Aimé, and from its records he deduced a rise and fall of 88 millim. (say  $3\frac{1}{2}$  in.) at springs and half that amount at neaps, a fluctuation which would escape ordinary observation, as it would be masked by the effects of atmospheric disturbances. At Venice and in the upper reaches of the Adriatic, the true lunisolar tide seems to be more accentuated than in other parts; but here also its effects are subordinate to those of the wind. In summer the Mediterranean is within the northern limit of the north-east trade wind; consequently, throughout a great part of the year, the winds are tolerably constant

in direction; and, blowing as they do over large areas of water, they are instrumental in moving large masses of it from one point to another, and so producing streams and currents.

The effect of wind on a surface of water is twofold: it produces the rhythmic motion of waves and the motion of translation of currents. Besides the motion produced by the direct action of the wind on the surface-water, there are currents due in the first instance to the accumulation of water produced by a wind which has been blowing constantly in one direction. The phenomenon of an abnormally high tidal rise with a gale of wind blowing on shore is one with which inhabitants of the British Islands are familiar. It is also a matter of frequent observation that, for instance, a south-west gale which exaggerates the height of high water on the western coasts of Britain reduces it on the east coasts. It blows the water on the west coast and off the east coast, so that the difference in the high-water levels on the two coasts is very pronounced. Supposing free communication were quickly made between the two coasts, a current would be the result, and its violence would be much greater than would be due to the local action of the wind on its surface. In the Mediterranean the winds blow during a great portion of the year very constantly from one direction or another, and generally from north and east. The extent of the sea is so great that the slope produced by the transference of the surface water constantly in one direction might have a sine or arc capable of being measured in feet and inches when the radius is as much as 200 miles long. Thus at Port Mahon, in the island of Minorca, according to the *Admiralty Sailing Directions*, the water rises and falls according to the direction of the wind. With wind from south-east or south-west the water rises, but from north-west or north-east it falls. When northerly or north-westerly winds prevail, and this is the case for two-thirds of the year, a strong current sets to the south-west off Ayre Island, which is reversed in seasons when south-westerly winds prevail. This current is due to the water escaping round the end of Minorca having been driven southward so as to raise a head on the north coasts of the island. Similarly in the Faro or Strait of Messina the currents, of which the famous Scylla and Charybdis are swirls or eddies, are the evidence of a tendency towards equalizing the levels of the eastern extremity of the western basin and of the western extremity of the eastern basin. In addition to this peculiarity of position with reference to the two basins, it has been found that there is a very strong purely tidal influence at work which alone produces an alteration in the direction of the currents, and thus adds to the confusion of the waters. At Capo di Faro the rise is scarcely perceptible, at Messina it may attain a maximum of 10 to 13 inches. In the Straits of Bonifacio, between Corsica and Sardinia, the currents follow entirely the direction of the prevailing winds, and are at times very rapid. In the channel between Sicily and the African coast the currents also follow the winds. In long periods of calm weather a steady easterly set is observed, no doubt a prolongation or reproduction of the Gibraltar current.

*Temperature.*—Nothing whatever was known of the temperature of the deep water of the Mediterranean until Saussure extended to it his classical investigation into that of the Swiss lakes. In October 1780 he sank his thermometer to a depth of 160 fathoms off Genoa and of 320 fathoms off Nice, and at both depths he found the temperature of the water to be 55°-8 F. These observations have a special value, for, owing to Saussure's method of experimenting, his results were not affected by the pressure obtaining at great depths in the sea. Fifty years elapsed before any similar experiments were made, when D'Urville, in the "Astrolabe," made a few observations at the beginning and the end of his famous expedition. There is some uncertainty about his observations in 1826 and 1829, and also about the later ones of Bérard in 1831, as

we are not informed whether the self-registering instruments used were protected from pressure or not. Mr Prestwich,<sup>1</sup> however, who has collected and critically discussed all the older deep-sea temperature observations, concludes, from a comparison of their results with those obtained by Aimé with protected instruments, that they were so protected, and admits their results into his tables without correction. In the deep water to the northward of the Balearic Islands D'Urville found in April 1826 54°·5 F. in 270 fathoms, and in March 1829 54°·7 at the same depth, and the same temperature (54°·7) in 530 fathoms. Bérard, experimenting in the sea between the Balearic Islands and Algeria, found the temperature of the deep water nearly a degree higher, namely 55°·4 F., in depths of 500 to 1000 fathoms. Aimé<sup>2</sup> relates his own careful experiments on the temperature of both surface and deeper water in the neighbourhood of Algiers, and discusses them in connexion with those of other observers with very great ability. He concludes from his own observations and those of Bérard that the uniform temperature at great depths is 54°·86 F. From a consideration of the general climate of the Mediterranean, he comes to the conclusion that the temperature in the deeper layers of the sea ought to be lower than the annual mean of the surface, and that it ought to be not very different from the mean surface temperature in the winter months. From observations at Toulon and Algiers, he finds that at neither place does the surface temperature fall below 50° F., and that the mean surface temperatures in the months December, January, February, March, and April is at Toulon 53°·06 F. and at Algiers 56°·84 F. The mean of these two temperatures is 54°·9 F., which is almost exactly what he finds to be the mean annual temperature of the deepest water of the western basin. During the forty years which have elapsed since Aimé made his experiments and speculations, further observations have only tended to confirm his theory. It is true that the temperatures observed in the many soundings which have been made of late years have not shown absolute identity of temperature, and it is probable that the greater refinement in the instruments used the more decided will the local differences appear. Especially it will be apparent that the bottom temperature varies with the climate of the preceding winter, and the distribution of temperature varies much with the prevalence of the winds. At the few stations where the temperature of the sea-water and that of the air are regularly examined, it appears that the water is generally for the greater part of the year warmer than the air, and in winter considerably so. The existing observations, however, are too few to justify any very definite statement on the subject. At Palermo the sea is warmer than the air throughout the whole year with the exception of the months May and June. In Algiers Aimé found but little difference; in autumn and winter the water was slightly warmer, in spring and summer slightly colder, than the air. In the eastern basin we have first Admiral Spratt's observations in July 1845 in Ægina Gulf. In all his experiments made previous to the year 1860 he determined the temperature of the bottom water by taking that of the mud brought up in the dredge. This is a very excellent method; in fact it is probably the best of all methods if a sufficient quantity of mud be obtained. From 1860 he used self-registering unprotected thermometers, which gave results necessarily too high, and it is impossible to apply any reliable correction to them without experimentally determining it on each thermometer which was used. By the first method Admiral Spratt found 55°·5 F. at depths between 100 and 200 fathoms.

From these observations it seemed reasonable to conclude, as Aimé had done, that all over the Mediterranean a practically uniform temperature is found at all depths greater than 100 or 200 fathoms, and that this temperature is 54° to 56° F. In order thoroughly to investigate this matter, as well as the biological conditions of the deep water of the Mediterranean, H.M.S. "Porcupine," Captain Calver, with Messrs Carpenter and Gwyn Jeffreys, visited the western basin of the Mediterranean in the autumn of 1870. A large number of temperature observations were made in the western basin near its southern coasts, and one sounding with temperature observation in the eastern basin a short distance from the Sicilian coast, the result of which was to confirm the conclusion arrived at from earlier observations, that, however high the temperature of the surface may be (and it may reach 90° F.), the water becomes rapidly cooler as we go below the surface until we reach a depth of about 100 fathoms, where a temperature of 54° to 56° F. is found, and persists without sensible variation to the greatest depths. The average of all the bottom temperatures in the western basin was 54°·88 F. Three soundings were made in the intermediate basin to the eastward of Pantellaria in depths of 266, 390, and 445 fathoms, and in each case the bottom temperature was found to be 56°·5 F., or about a degree and a half warmer than in the deeper western basin. This is precisely what might have been expected from what we know of inland seas divided into several basins. In summer the shallower basin has usually a higher temperature at the bottom

than is found at the same depth in the deeper one. Only one observation was made in the eastern basin, namely off Cape Passaro, in 1743 fathoms, with a bottom temperature of 56°·0 F. That the temperature in this basin should be lower than in the Pantellaria basin is due to its greater depth, and that it should be higher than is found in the western basin is due to its lower latitude. These researches were further prosecuted in the autumn of 1871 in the "Shearwater," Captain Nares, accompanied by Dr Carpenter. At two stations in the eastern basin "serial temperatures" were taken. At the first, 35° 54' N. lat., 16° 23' E. long., depth 1650 fathoms, the bottom temperature was 56°, or the same as had been observed the year before in 1743 fathoms; at the second, 32° 17½' N. lat., 26° 44' E. long., depth 1970 fathoms, the bottom temperature was 56°·7, and the temperature at all intermediate depths was much higher than at the first station. The mean temperature of the water from the surface to a depth of 200 fathoms was, at the first station, 63°·75 F., and + the second 66°·78 F., or three degrees higher. At the first station all the temperatures down to 100 fathoms are higher than were observed in 1870 in the western basin, but it must be remembered that temperature observations made in different years cannot with justice be closely compared, as the climates of the two years are sure to differ considerably, and in the present case the difference in climate between the summers of 1870 and 1871 appears to have been very considerable.

In the autumn of 1881 a very interesting series of observations were made by Captain Magnaghi, hydrographer of the Italian navy, and Professor Giglioli, on board the Italian surveying ship "Washington," in that part of the western basin which is enclosed between the islands Corsica and Sardinia on the one side and the Italian coasts on the other. It is here that the deepest water of the western basin was found; and, apart from the great interest attaching to the physical results obtained, the collections made with the dredge in the comparatively lifeless waters were of the very highest importance, showing, as they did, a practical identity in the abyssal fauna with that of the open ocean. This is the more remarkable as we have hitherto been accustomed to consider the similarity in the fauna of portions of the ocean remotely distant from each other as being due to the likeness of their temperatures. In the Mediterranean, however, the bottom temperature is quite 20° F. higher than is found in great depths anywhere in the open ocean.

For determining the temperature of the deep water Captain Magnaghi used the half-turn reversing thermometer of Negretti and Zambra, which in itself is a very beautiful instrument. The mechanical arrangement, however, for reversing, even as improved by Magnaghi, was not so satisfactory, and from certain irregularities in the temperature observations reported the writer is inclined to think that some of the remarkable results obtained, for instance on the 11th August, are due to this instrumental imperfection. On that day the water at 70 metres was found to have a temperature of 25°·1 C., while that at 50 metres was 20°·1 C., and that at 90 metres was 16°·7 C. The results obtained in the deep water are no doubt quite reliable, for the temperature is so uniform that a few fathoms more or less in the depth at which it turned would make no difference in the temperature registered. In the more northern parts of this portion of the western basin, off the coast of Corsica, we find a practically uniform temperature from 250 metres down to the bottom in 2800 metres, the mean bottom temperature being 55°·96 F. Further to the south the temperature of the abyssal water appears to be distinctly higher. Thus between the south end of Sardinia and the Bay of Naples, in the deepest water, the practical uniformity of temperature is not reached until a depth of 1000 metres has been passed, and it is there 56°·7 F. It is unfortunate that we do not know what the bottom temperature in other parts of the Mediterranean was. In this summer of 1881 it was quite one degree higher than that observed by Dr Carpenter in 1870.

The great value of such a volume of water as an equalizer of temperature on its shores must be apparent, though in this respect it is inferior to the Atlantic Ocean in its immediate neighbourhood. Places on the west coast of Spain and Portugal have a much higher winter temperature and lower summer temperature than places in the same latitude in Italy. The reason of this is simple: on the Atlantic coast the principal winds in winter are from the south-west, and have a warming effect, while in summer the source of the north-east trade wind is pushed back into the Bay of Biscay, causing in this season constant northerly winds along the coast of Portugal. The winds of the Mediterranean have no seas of remote latitudes to draw on either for heating or cooling purposes, though the sandy deserts of Africa which bound its southern coasts have at certain seasons a very decided influence on the climate. The tempering action of the sea does not extend very far inland, as is evident from the climate of inland towns in Italy. As the Mediterranean shores have so much importance as health-resorts, the data presented in the following table are of interest. They are taken chiefly from Theobald Fischer's *Studien über das Klima der Mittelmeerlande*.

*Nature of the Bottom.*—In the western basin the bottom consists chiefly of clay of a grey to brownish colour. Without doubt, when freshly collected, the surface layer is reddish-brown and the lower ones dark grey. There is always some carbonate of lime, chiefly due to *Foraminifera*. The mud very much resembles that obtained from similar depths in those parts of the open ocean whose bottom waters are shut off from free communication by ridges which may not approach within 2000 or 1500 fathoms of the surface, and with the exception of the *Foraminifera* it much resembles the mud from enclosed and comparatively shallow basins off the west coast of Scotland. In the following table the analyses are given of a few samples on the line of the submarine cable connecting Marseilles with Algiers.

To the student of the physical conditions of the sea the Mediterranean possesses a very high interest; its size is such as to entitle it to rank among oceans, while it is so completely cut off from the remaining world of water that it presents us with a type which is purely local, and one might almost say provincial. (J. Y. B.)

**MEDLAR**, *Mespilus Germanica*, L., of the tribe *Pomæ* of the order *Rosaceæ*, regarded by Bentham and Hooker as a subgenus of *Pyrus* (*Gen. Pl.*, i. 626; see also DC., *Prod.*, ii. 633; *Trans. Linn. Soc.*, xiii. 99), is a native of European woods, &c., from Holland southwards, and of western Asia (London, *Arb.*, ii. 877). It occurs in hedges, &c., in middle and south England, as a small much-branched spinous tree, but is not indigenous to Great Britain (Hooker's *Stud. Fl. of Br. Isles*, 132; Baxter's *Brit. Gen. of Pl.*, 493, and *Mag. Nat. Hist.*, vol. ix. 86). The medlar was well known to the ancients. Pickering (*Chron. Hist. of Pl.*, 201) identifies it with a tree mentioned in a Siao-ya ode (*She-King*, ii. 1, 2), 827 B.C. It is the *μειλίρη* of Theophrastus and *Mespilus* of Pliny. Loudon (*l.c.*) gives three varieties, *diffusa*, *stricta*, and *sylvestris*,—the last being spiny, but losing its spines under cultivation, —as well as four varieties of fruit. He also mentions several instances of large specimens throughout England. The well-known fruit is globular, but depressed above, with leafy persistent sepals, and contains stones of a hemispherical shape. It is not fit to eat until it begins to decay. (For culture of the medlar see **HORTICULTURE**.) The Japanese medlar is *Eriobotrya japonica*, L., a genus of the same tribe of *Rosaceæ*.

**MÉDOC** is the name given to the district in France adjoining the left bank of the Gironde from Ambès, the point where the Garonne and Dordogne unite, to Lesparre, where the marshes and polders which border on the mouth of the river begin; its length varies from 35 to 40 miles, its breadth from 12 to 5, and the area is about 386 square miles. It is formed by a number of low hills, which separate the Landes from the Gironde, and is traversed only by small streams; the Gironde itself is muddy, and often enveloped in fog, and the region as a whole is very far from being picturesque; but a fifth part of its soil is occupied by vineyards, the products of which form the finest growths of Bordeaux. Of these the most esteemed are Château-Margaux, Château-Lafitte, and Château-Latour. Prior to the ravages of the *Phylloxera*, the annual product of the Médoc district was 40,000 tuns, of which 9000 were of fine quality.

**MEDUSA**. See GORGON, vol. x. p. 785. See also HYDROZOA, vol. xii. p. 547 sq.

**MEDYN**, a district town of Russia, situated in the government of Kaluga, 39 miles north-west of the capital of the province, on the highway from Moscow to Warsaw. It was formerly known under the name of Mezetsk, and in the 14th century formed part of the Smolensk principality. The soil of the surrounding country being rather infertile, the population is engaged to some extent in manufactures of linen, cotton, and paper, and the merchants of Medyn carry on a brisk trade in this produce, as well as in rye, oats, and hemp seed. The population is 8000.

**MEER**, JAN VAN DER (1632–1675), of Delft,—not to be confounded with the elder or younger Van der Meer of Haarlem or with Van der Meer of Utrecht,—is one of the excellent painters of Holland about whom the Dutch biographers give us little information.<sup>1</sup> Van der Meer, or Vermeer, by which name he is also known, was born in Delft in 1632. There is a tradition, handed down by the Dutch writers, that he was a pupil of Carel Fabritius, but, in the strict sense of the word, this is almost impossible, for Fabritius was but eight years older than Van der Meer, and entered the guild of St Luke only one year before our painter. From his early death the works by Fabritius are few, but his contemporaries speak of him as a man of remarkable power, and the paintings now ascertained to be from his hand, and till recently ascribed to Rembrandt, prove him to have been deeply imbued with the spirit and manner of that master. Whether Van der Meer had ever any closer relation to Rembrandt than through companionship with Fabritius remains as yet uncertain. In 1653 he married Catherine Bolones, and in the same year he entered the guild of St Luke of Delft, becoming one of the heads of the guild in 1662, and again in 1670. He died at Delft in 1675, leaving a widow and eight children. His circumstances cannot have been flourishing, for at his death he left twenty-six pictures undisposed of, and his widow had to apply to the court of insolvency to be placed under a curator, who, it is interesting to know, was Leeuwenhoek, the naturalist.

It is his works, however, that claim our attention. For more than two centuries he has been almost completely forgotten, and his pictures have been sold under the names

<sup>1</sup> This undeserved neglect seems to have fallen on him at an early period, for Houbraken (*Groote Schouburgh*, 1718), writing little more than forty years after his death, does not even mention him. The only definite information we have from a contemporary is given by Bleywijck (*Beschrijving der Stad Delft*, 1687), who tells us that he was born in 1632, and that he worked along with Carl Fabritius, an able disciple of Rembrandt, who lost his life by an explosion of a powder magazine in Delft in 1654. It is to the patient researches of W. Bürger (Th. Thoré), Havard, Obreen, Soutendam, and others that we owe our knowledge of the main facts of his life, discovered in the archives of his native town.

and forged signatures of the more popular De Hooch, Metzu, Terborch, and even of Rembrandt. The honour of first recalling the attention of the art-world to this most original painter belongs undoubtedly to Thoré, an exiled Frenchman, who described his then known works in his *Musées de la Hollande* (1858-60), published under the assumed name of W. Bürger. The result of his researches, continued in his *Galerie Suermondt* and *Galerie d'Arenberg*, was afterwards given by him in a charming, though incomplete, monograph (*Gazette des Beaux-Arts*, 1866, pp. 297, 458, 542). The task has since been prosecuted with success by Havard (*Les Artistes Hollandais*), and by Obreen (*Nederlandsche Kunstgeschiedenis*, Dl. iv.), and we are now in a position to refer to Van der Meer's works. His pictures are rarely dated, but, luckily for us, one of the most important bears the date 1656, and thus gives us a key to his styles. The picture referred to is the only one that has figures of life size. It is the Woman and Soldier, with other two figures, of the Dresden gallery, and is painted with remarkable power and boldness, great command over the resources of colour, and with wonderful expression of life. For strength and colour it more than holds its own beside the neighbouring Rembrandts. To this early period of his career belong, from internal evidence, the Reading Girl of the same gallery, the luminous and masterly view of Delft in the museum of the Hague, La Laitière and the small street view, both in the collection of M. Six van Hillegom at Amsterdam, Le Soldat et la Fillette qui Rit of M. Double, the Country House in the gallery at Berlin, and others. In all these we find the same brilliant style and vigorous work, a solid impasto and a crisp sparkling touch. His first manner seems to have been influenced by the pleiad of painters circling round Rembrandt, a school which we know lost favour in Holland in the last quarter of the century. During the last ten or twelve years of his life Van der Meer adopted a second manner. We now find his painting smooth and thin, and his colours paler and softer. Instead of masculine vigour we have refined delicacy and subtlety, but in both styles beauty of tone and perfect harmony are conspicuous. Through all his work may be traced his love of lemon-yellow and of blue of all shades. Of his second style typical examples are to be seen in La Coquette of the Brunswick gallery, in the Woman Reading in the Van der Hoop collection at the Hague, in the Lady at a Casement belonging to Lord Powerscourt (exhibited at Burlington House, 1878), and in the Music Master and Pupil belonging to the Queen (exhibited at Burlington House, 1876).

Van der Meer's works are extremely rare. There is but one in the Louvre, the Lace Maker; Dresden has the two above-mentioned, while Berlin has three, all acquired in the Suermondt collection, and the Czernin gallery of Vienna is fortunate in possessing a fine picture, believed to represent the artist in his studio. In the Arenberg gallery at Brussels there is a remarkable head of a girl, half the size of life, which seems to be intermediate between his two styles. Several of his paintings are to be found in private foreign collections. In all his work there is a singular completeness and charm. In rendering momentary expression he is a master, and his pictures attract by the perfect delineation of character as well as by the technical skill of the painter. His tone is usually silvery with pearly shadows, and the lighting of his interiors is equal and natural. In all cases his figures seem to move in light and air, and in this respect he resembles greatly his fellow-worker De Hooch, who entered the guild of St Luke only two years later than Van der Meer. It is curious to read that, at one of the auctions in Amsterdam about the middle of last century, a De Hooch is praised as being "nearly equal to the famous Van der Meer of Delft." So nearly are they allied that the best judges are divided in opinion whether the Dutch Family ("La Promenade") of the academy of Vienna should be attributed to our painter or to De Hooch. Doubtless many of Van der Meer's works have yet to be restored to their proper author; but, as he is now in vogue, much care will

have to be used in judging. This is specially true in regard to the landscapes and "still life" subjects which are attributed to him. The task is made more difficult by the diversity of style of this "Protean painter," as he is called by Dr Waagen, or, as Bürger names him, "the Sphinx of Delft." (J. F. W.)

**MEERANE**, a rapidly increasing industrial town in south-eastern Saxony, lies in the district of Zwickau, about 37 miles to the south of Leipsic. It contains an old church, a "Realschule," and a technical school for weavers. The leading industry is the weaving of woollen and half-woollen cloth, employing 3000 power-looms and 15,000 hand-looms, and producing goods of the annual value of upwards of £200,000. A large proportion of the cloth is exported to America and Japan. Meerane also possesses several important dye-works, besides smaller industrial establishments of various kinds. The population in 1880 was 22,293.

**MEERSCHAUM**. This German name is applied to a certain mineral, in consequence of its lightness, softness, and white colour, which suggest a resemblance to "sea foam." In like manner it is called in French *écume de mer*. By the German mineralogist Glocker it was termed *sepiolite*, in allusion to its resemblance to the so-called bone of the sepia or cuttle-fish. Possibly the fact that pieces of meerschaum, washed out of their matrix, are occasionally found floating on the Black Sea, may have led to the association of the mineral with marine products. Meerschaum is an opaque earthy mineral, of white, greyish, or yellowish colour, compact in texture, and breaking with a conchoidal or fine earthy fracture; it adheres to the tongue, and is so soft as to be scratched by the nail, its degree of hardness being about 2 or 2.5. Its specific gravity varies from 0.988 to 1.279; hence it floats in sea-water until saturated. Meerschaum is a hydrated silicate of magnesium, represented by the formula  $Mg_2Si_2O_8 + nH_2O$ . The value of  $n$ , according to some analyses, is 2. Most of our meerschaum comes from Asia Minor, especially from the plains of Eski-shehr, where it occurs in nodular masses, of variable size and irregular shape, distributed through the alluvial deposits of the plain, which are systematically worked for its extraction by means of pits and galleries. The mineral is associated with magnesite, or carbonate of magnesium, and has probably been derived from the neighbouring mountains, where a similar carbonate is found in connexion with serpentine. Meerschaum is found also, though less abundantly, in Greece and in some of the Grecian islands; at Hrubshitz in Moravia, where it occurs in a serpentinous matrix; and in Morocco, where it is used, when soft and fresh, as a substitute for soap; while a coarse variety is found at Vallecás near Madrid, and is employed as a building stone. Meerschaum also occurs in South Carolina.

By far the greatest quantity of meerschaum is used in the manufacture of tobacco-pipes, a purpose for which it is well fitted by its porosity. The nodular masses are first roughly scraped in order to remove the red earthy matrix; they are then dried, scraped again, and finally polished with wax. In this state the rudely-shaped nodular pieces are sent from the East principally to Vienna and to various parts of Germany. The pipe-bowls, after having been turned and carved, are rubbed with glass-paper and Dutch rushes; they are next boiled in wax, spermaceti, or stearine, and afterwards subjected to careful polishing with bone-ash, chalk, &c.

An imitation of meerschaum for common pipes is made of hardened plaster of Paris, treated with paraffin, and coloured by gamboge and dragon's blood. A peculiar preparation, into which potato largely enters, is said to have been successfully employed in France as a substitute for meerschaum.

**MEERUT**, or **MIRATH**, a district in the division<sup>1</sup> of

<sup>1</sup> The division lies between 27° 38' and 30° 57' N. lat., and between 77° 7' and 78° 42' E. long., and comprises the six districts of Dehra Dun, Sahāranpur, Muzaffarnagar, Meerut, Bulandshahr, and Aligarh. The area in 1878 was 11,138 square miles, and the population in 1872 4,977,178.

Meerut and the lieutenant-governorship of the North-Western Provinces, India, lying between 28° 28' and 29° 18' N. lat., and 77° 10' and 78° 14' E. long., is bounded on the N. by Muzaffarnagar district, on the E. by the Ganges, on the S. by Bulandshahr district, and on the W. by the Jumna. The area in 1881 was given as 2361 square miles. Meerut forms a portion of the long and narrow plain lying between the Ganges and the Jumna, with a very gentle slope from north to south. Though well wooded in places and abundantly supplied with mango groves, it has but few patches of jungle or waste land to break the general expanse of cultivated soil. Sandy ridges run along the low watersheds which separate the minor channels, but with this exception the whole district is one continuous expanse of careful and prosperous tillage. Its fertility is largely due to the system of irrigation canals, which intersect it in every direction. The eastern Jumna canal runs through the whole length of the district, and supplies the rich tract between the Jumna and the Hindan with a network of distributary streams. The main branch of the Ganges canal passes across the centre of the plateau in a sweeping curve, and waters the midland tract. The Anúpshahr branch supplies irrigation to the Ganges slope. Besides these natural and artificial channels, the country is everywhere cut up by small water-courses. The Burh Gangá, or ancient bed of the Ganges, lies at some distance from the modern stream; and on its bank stood the abandoned city of Hastinapur, the legendary capital of the Pandavas at the period of the *Mahábhárata*, said to have been deserted many centuries before the Christian era, owing to the encroachments of the river.

The census of 1872 returned the population of the district at 1,276,104, the Hindus numbering 991,226. Among the higher castes Bráhmans muster strong (109,804). The Rájputs (both Hindus and Mohammedans) number 55,088, and enjoy great social distinction as landholders; the Baniás, or traders (66,942), also now hold considerable landed property. The great cultivating castes are the Chamárs (197,273) and Játs (145,514). The Gujars (60,350) are a pastoral tribe, with an ancient character for plunder and cattle-lifting, which is now passing away. The Mohammedans (281,857) are for the most part the descendants of converted Hindus. The Christian population consists of 2149 Europeans, 142 Eurasians, and 730 natives. Fifteen towns in the district contain a population exceeding 5000; namely, Meerut, 81,386; Hápúr, 14,544; Sardhána, 12,466; Garhmukhtesar, 7962; Bágpat, 7367; Ghaziábád, 7365; Shahdara, 7257; Baro, 7056; Mawana, 6864; Pilkhua, 6239; Khekara, 6045; Tikri, 5698; Kirthal, 5651; Dasma, 5605; Chaprauli, 5594.

Meerut is one of the most flourishing and best tilled districts of the Doáb. Out of a total area of 1,505,824 acres, as many as 1,048,221 were under cultivation in 1881, 281,095 acres being irrigated by Government works, and 808,526 by private individuals. The grazing lands comprehended 242,091 acres, and the waste 185,400. The condition both of agricultural labourers and of artisans and workmen in the towns has considerably improved of late years. About one-half the soil is cultivated by the proprietors themselves, the remainder being about equally divided between tenants with occupancy rights and tenants-at-will. Rents are paid in money, and range from 18s. 10d. per acre for the best canal-watered lands down to 2s. 5½d. per acre for "dry" unirrigated soils. The chief exports of the district are grain, cotton, and indigo; and the principal imports are Manchester goods, English hardware, tobacco, drugs, and spices. The chief commercial centres are Meerut, Ghaziábád, and Bágpat. Besides the great waterways of the Jumna and Ganges, and the navigable canals, communication is afforded by the East Indian and the Punjab and Delhi Railways; also by 1505 miles of made roads. In 1876 the district was in the administrative charge of four covenanted civilians, and contained seventeen magisterial and fifteen civil courts. The gross revenue in 1881 was £248,754, of which £203,977 was derived from the land-tax; the cost of officials and police was £27,520. In 1881 there were 214 schools, attended by 6677 pupils. The comparatively high latitude and elevated position of Meerut make it one of the healthiest districts in the plains of India. The average temperature varies from 57° Fahr. in January to 87° in June. The rainfall is small, less than 30 inches annually. The only endemic disease in the district is malarial fever; but small-pox and cholera occasionally visit it as epidemics.

The authentic history of the district commences with the

Moslem invasions. Until the 11th century it is probable that Meerut was mainly in the hands of predatory native tribes, such as the Játs and Dors. The first undoubted Mohammedan invasion was that of Kutab-ud-din in 1191, when Meerut town was taken, and all the Hindu temples turned into mosques. In 1398 Timúr swooped down upon the district, captured the fort of Loni after a desperate resistance, and put all his Hindu prisoners to death. He then proceeded to Delhi, and after his memorable sack of that city, returned to Meerut, captured the town, razed all the fortifications and houses of the Hindus, and put the male inhabitants to the sword. The firm establishment of the great Mughal dynasty in the 16th century, under Bábar and his successors, gave Meerut a period of internal tranquillity and royal favour. After the death of Aurangzeb, however, it was exposed to alternate Sikh and Mahrattá invasions. From 1707 till 1775 the country was the scene of one perpetual strife, and was only rescued from anarchy by the exertions of the military adventurer Walter Reinhardt, afterwards the husband of the celebrated Begüm Samru, who established himself at Sardhána in the north, and ruled a large estate. The southern tract, however, remained in its anarchic condition under Mahrattá exactions until the fall of Delhi in 1803, when the whole of the country between the Jumna and the Ganges was ceded by Sindhia to the British. It was formed into a separate district in 1818. In the British period it has become memorable as being the place where the first outbreak of the great mutiny of 1857 took place.

MEERUT, a city and cantonment in the above district, is situated about half way between the Ganges and the Jumna, in 29° 0' 41" N. lat. and 77° 45' 3" E. long. The city proper lies south of the cantonments, and although a very ancient town, dating as far back as the days of the Buddhist emperor Asoka (*circ.* 250 B.C.), Meerut owes its modern importance to its selection by the British Government as the site of a great military station. In 1805 it is mentioned as "a ruined depopulated town." The cantonment was established in 1806, and the population rose rapidly to 29,014 in 1847, and 82,035 in 1853. In 1872 the census returned the population (exclusive of the military) at 81,386, viz., Hindus, 47,606; Mohammedans, 33,532; Christians, 248. The slight decline of population between 1853 and 1872 may probably be attributed to the mutiny of 1857. Most of the streets have a poor appearance, owing to the hasty manner in which they were erected. The cantonment, a little to the north of the city, forms the headquarters of a military division. The principal building is the Meerut church with its handsome tall spire. There are also a Roman Catholic church, mission chapel, asylum for the relief of Europeans and Christians, and a club. The Mall is one of the finest drives in India.

MEGALOPOLIS, a city of southern Arcadia, situated in a plain about 20 miles south-west of Tegea, on both banks of the Helisson, about 2½ miles above its junction with the Alpheus. Like Messene, it owed its origin to Epaminondas, and was founded in 370 B.C., the year after the battle of Leuctra, as a bulwark for the southern Arcadians against Sparta, and as the seat of the Arcadian federal diet, which consisted of ten thousand men. The builders of the city were protected by a Theban force, and directed by ten native oecists, who likewise attended to the peopling of the new city, which apparently drew inhabitants from all parts of Arcadia, but more especially from the neighbouring districts of Mænalia and Parrhasia. Forty townships are mentioned by Pausanias (viii. 27, 3-5) as having been incorporated in it. It was fifty stadia in circumference, and was surrounded with strong walls. Its territory was the largest in Arcadia, extending northward 24 miles. The city was built on a magnificent scale, and adorned with many handsome buildings, both public and private. Its temples contained many ancient statues brought from the towns incorporated in it. On the north side of the Helisson, which divided it into two nearly equal parts, was the agora with four porticos, the gymnasium, a sacred grove, temples to the Lycæan Zeus, Pan Oinoëis, Rhea, Tyche, the great goddesses (Demeter and Core), Zeus Philios (with a statue by Polycleus), Aphro-

dite, Core, Athena Polias, and Hera Teleia. Among the numerous statues which stood in the open air the finest was that of Apollo Epicurius, 12 feet high, brought from the beautiful temple of Bassæ, which was built by Ictinus, and is still in great part standing. On the south side of the river were the theatre, the largest in Greece, the Thersilion or hall for the assembly of the Arcadian diet, a house built for Alexander the Great, with a statue of Zeus Ammon, the stadium, temples to the Muses, Apollo, and Hermes, to Aphrodite, to Ares, to Dionysus, to Hercules and Hermes, to Artemis Agrotera, to Asclepius and Hygiea, to the son of Asclepius, and to Apollo. Of all these buildings, with the exception of the theatre, hardly a trace remains above ground. The ruins of Megalopolis are near Sinanou.

The foundations of Megalopolis were hardly laid when Agesilaus undertook an expedition in the hope of breaking up the union of which it was the visible sign and capital. He accomplished nothing, and had hardly reached home when the Thebans and their allies under Epaminondas and Pelopidas entered the Peloponnese and marched through Laconia almost unopposed. After the departure of Epaminondas, Lycomedes of Mantinea succeeded in drawing the Arcadian federation away from its alliance with Thebes, in consequence of which it had to make common cause with Athens. An attempt on the part of the federation to use the treasures of the temple of Zeus at Olympia led to internal dissensions, so that in the battle of Mantinea (362) one half of the Arcadians fought on the side of the Spartans, the other on that of the Thebans. After this battle many of the inhabitants of Megalopolis sought to return to their former homes, and it was only by the assistance of three thousand Thebans under Pammenes that the authorities were able to prevent them from doing so. In the year 352, when Thebes had her hands full with the so-called Sacred War, the Spartans made an attempt to reduce Megalopolis; but the Thebans promptly sent assistance, and the city was rescued. Not sure of this assistance, the Megalopolitans had appealed to Athens, an appeal which gave occasion to Demosthenes's oration *Περὶ Μεγαλοπολιτῶν*. The Spartans were now obliged to conclude peace with Megalopolis and acknowledge her autonomy. Nevertheless their feeling of hostility did not cease, and Megalopolis consequently entered into friendly relations with Philip of Macedon. Twenty years later, when the Spartans and their allies rebelled against the power of Macedon, Megalopolis remained firm in its allegiance, and was subjected to a siege of considerable duration. After the death of Alexander, Megalopolis was governed by native tyrants. In the war between Cassander and Polysperchon it took part with the former, and was, in consequence, besieged by the latter. On this occasion it was able to send into the field an army of fifteen thousand. In 234 B.C. Lydiades, the last tyrant of Megalopolis, voluntarily resigned his power, and the city joined the Achæan league. In consequence of this it was once more exposed to the bitter hatred of Sparta. In 222 Cleomenes took and plundered it, and killed or dispersed its inhabitants, but in the year following it was restored and its inhabitants reinstated by Philopomen, a native of the city. At this time the circuit of its walls always too great, seems to have been contracted. At all events it never again attained political importance, and gradually sank into insignificance. The only great men whom it produced were Philopomen and Polybius the historian. Lycortas, the father of the latter, may be accounted a third. In the time of Pausanias the city was mostly in ruins.

MEGALOSAURUS. See REPTILES.

MEGAPODE, the name given generally to a small but remarkable Family of birds, highly characteristic of some parts of the Australian Region, to which it is almost peculiar. The *Megapodidæ* with the *Cracidæ* form that division of the Order *Gallinæ* named by Professor Huxley *Peristeropodes* (*Proc. Zool. Society*, 1868, p. 296), and morphologically seem to be the lowest of the Order, with which apparent fact may perhaps be correlated their singular habit of leaving their eggs to be hatched without incubation, burying them in the ground (as many Reptiles do) or heaping over them a mound of earth, leaves, and rotten wood. This habit attracted attention more than three hundred years ago,<sup>1</sup> but the accounts given of it by various

travellers were generally discredited by naturalists,<sup>2</sup> and as examples of the birds, probably from their unattractive plumage, appear not to have been brought to Europe, no one of them was seen by any ornithologist or scientifically described until near the end of the first quarter of the present century. The first member of the Family to receive authoritative recognition was one of the largest, inhabiting the continent of Australia, where it is known as the Brush-Turkey, and was originally described by Latham in 1821 under the name of the New-Holland Vulture, a misleading designation which he subsequently tried to correct on perceiving its Galline character. It is the *Talegallus lathamii* of modern ornithologists, and is nearly the size of a hen Turkey. Six smaller species of the same genus have since been described, all from New Guinea or the neighbouring islands, but two of them, *T. pyrrhopygius* and *T. bruynei*, have been separated to form a group *Epypodius*. The Australian bird is of a sooty-brown colour, relieved beneath by the lighter edging of some of the feathers, but the head and neck are nearly bare, beset with fine bristles, the skin being of a deep pinkish-red, passing above the breast into a large wattle of bright yellow. The tail is commonly carried upright and partly folded, something like that of a domestic Fowl.

The next form of which we may speak is another inhabitant of Australia, commonly known in England as the Mallee-bird, but to the colonists as the "Native Pheasant"—the *Lipoa ocellata*, described by Gould in the zoological *Proceedings* for 1840 (p. 126), which has much shorter tarsi and toes, the head entirely clothed, and the tail expanded. Its plumage presents a pleasing combination of greys and browns of various tints, interspersed with black, white, and buff, the wing-coverts and feathers

which laid its eggs, as big as a Duck's, in the sand, and left them to be hatched by the heat of the sun (*Premier Voyage autour du Monde*, ed. Amoretti, Paris, A.R. ix. p. 88). More than a hundred years later the Jesuit Nieremberg, in his *Historia Naturæ*, published at Antwerp in 1635, described (p. 207) a bird called "Daie," and by the natives named "Tapun," not larger than a Dove, which, with its tail (!) and feet, excavated a nest in sandy places and laid therein eggs bigger than those of a Goose. The publication at Rome in 1651 of Hernandez's *Hist. Avium Novæ Hispaniæ* shows that his papers must have been accessible to Nieremberg, who took from them the passage just mentioned, but, as not unusual with him, misprinted the names which stand in Hernandez's work (p. 56, cap. 220) "Daic" and "Tapun" respectively, and omitted his predecessor's important addition "Viuit in Philippicis." Not long after, the Dominican Navarrete, a missionary to China, made a considerable stay in the Philippines, and returning to Europe in 1673 wrote an account of the Chinese empire, of which Churchill (*Collection of Voyages and Travels*, vol. i.) gave an English translation in 1704. It is therein stated (p. 45) that in many of the islands of the Malay Archipelago "there is a very singular bird call'd *Tapon*," and that "What I and many more admire is, that it being no bigger in Body than an ordinary Chicken, tho' long legg'd, yet it lays an Egg larger than a Gooses, so that the Egg is bigger than the bird itself. . . . In order to lay its Eggs, it digs in the Sand above a yard in depth; after laying, it fills up the hole and makes it even with the rest; there the Eggs hatch with the heat of the Sun and Sand." He adds further information which need not be quoted here. Gemelli Careri, who travelled from 1663 to 1699, and in the latter year published an account of his voyage round the world, gives similar evidence respecting this remarkable bird, which he calls "Tavon," in the Philippine Islands (*Voy. du tour du Monde*, ed. Paris, 1727, v. pp. 157, 158). The Megapode of Luzon is fairly described by Camell or Camelli in his observations on the Birds of the Philippines communicated by Pétiver to the Royal Society in 1703 (*Phil. Trans.*, xxiii. p. 1398). In 1726 Valentyn published his elaborate work on the East Indies, wherein (deel iii. bk. v. p. 320) he very correctly describes the Megapode of Amboina under the name of "Malleloe," and also a larger kind found in Celebes, so as to shew he had in the course of his long residence in the Dutch settlements become personally acquainted with both.

<sup>2</sup> Thus Willughby (*Ornithologia*, p. 297), or Ray for him, who had, however, only Nieremberg's evidence to cite, and they can scarcely be blamed for their hesitation, considering the number of other marvels narrated by the same worthy father. Buffon also (*Oiseaux*, ix. p. 436) was just as sceptical in regard to the relation of Careri.

<sup>1</sup> Antonio Pigafetta, one of the survivors of Magellan's glorious but disastrous voyage, records in his journal, under date of April 1521, among the peculiarities of the Philippine Islands, then first discovered by Europeans, the existence of a bird there, about the size of a Fowl,

of the back bearing each near the tip an oval or subcircular patch, whence the trivial scientific name of the bird is given, while a stripe of black feathers with a median line of white extends down the front of the throat, from the chin to the breast. There is but one species of this genus known, as is also the case with the next to be mentioned, which is a singular bird long known to inhabit Celebes, but not fully described until 1846,<sup>1</sup> when it received from Salomon Müller (*Arch. f. Naturgeschichte*, xii. pt. 1, p. 116) the name of *Macrocephalon maleo*, but, being shortly afterwards figured by Gray and Mitchell (*Gen. Birds*, iii. pl. 123) under the generic term of *Megacephalon*, has since commonly borne the latter appellation. This is a very remarkable form, bearing a helmet-like protuberance on the back of its head, all of which as well as the neck is bare and of a bright red colour; the plumage of the body is glossy black above, and beneath roseate-white.

Of the Megapodes proper, constituting the genus *Megapodius*, many species have been described, but authorities are greatly at variance as to the validity of several, and here it would be impossible to name all that have been supposed to exist. Some are only known from very young examples—mere chickens; and some have even been described from their eggs alone. In 1870 Mr G. R. Gray enumerated twenty species, of which sixteen were represented in the British Museum, and several have been described since; but ten years later Professor Schlegel recognized only seventeen species, of which examples of twelve were contained in the Leyden Museum (*Mus. des Pays-Bas*, viii., Monogr. 41, pp. 56–86), while M. Oustalet, in his elaborate monograph of the Family (*Ann. Sc. Nat., Zoologie*, ser. 6, vols. x. and xi.), admits nineteen species. The birds of this genus range from the Samoa Islands in the east, through the Tonga group, to the New Hebrides, the northern part of Australia, New Guinea and its neighbouring islands, Celebes, the Pelew Islands, and the Ladrones, and have also outliers in detached portions of the Indian Region, as the Philippines (where indeed they were first discovered by Europeans), Labuan, and even the Nicobars—though none are known from the intervening islands of Borneo, Java, or Sumatra. Within what may be deemed their proper area they are found, says Mr Wallace (*Geogr. Distr. Animals*, ii. p. 341) “on the smallest islands and sand-banks, and can evidently pass over a few miles of sea with ease.” Indeed proof of their roaming disposition is afforded by the fact that the bird described by Lesson (*Voy. Coquille: Zoologie*, p. 703) as *Alecthelia urvillii*, but now considered to be the young of *Megapodius freycineti*, flew on board his ship when more than 2 miles from the nearest land (Guebé), in an exhausted state, it is true, but that may be attributed to its extreme youth. The species of *Megapodius* are about the size of small Fowls, the head generally crested, the tail very short, the feet enormously large, and, with the exception of *M. wallacii* (*Proc. Zool. Society*, 1860, *Aves*, pl. 171), from the Moluccas, all have a sombre plumage.

The extraordinary habit possessed by the Megapodes generally of relieving themselves of the duty of incubation, as before mentioned,—a habit which originally attracted the attention of travellers, whose stories were on that very account discredited,—as well as the highly developed condition of the young at birth, has been so fully described by Gould (*Handb. B. Australia*, ii. pp. 152–175), G. R. Gray (*Proc. Zool. Society*, 1861, pp. 292–296), and Mr Wallace (*Malay Archipelago*, i. pp. 415–419; ii. pp. 147–149), and so often repeated by other writers, as to

be very commonly known, and here there seems no necessity to enter into further details concerning it. (A. N.)

MEGARA was the name of two Greek towns, one in Sicily, which has been already described under HYBLA, the other on the road from Attica to Corinth. The country which belonged to the city was called *Μεγαρίς* or *ἡ Μεγαρικὴ*; it occupied the broader part of the isthmus between Attica, Boeotia, Corinth, and the two gulfs, and its whole area is estimated by Clinton at 143 square miles. The range of Mount Geraneia extends across the country from east to west, forming a barrier between continental Greece and the Peloponnesus. The shortest road across this range passes along the eastern side of the mountains, and the most difficult part is the celebrated Scironian rocks, the mythic home of the robber Sciron. The only plain in the rugged little country was the White Plain, in which was situated the only important town, Megara. The town was one of the most important commercial and colonizing centres of Greece in early times, and there is no doubt that its trade, like that of Corinth, owed its origin to the Phoenicians, who found its situation on the isthmus convenient. It became a Dorian city when that tribe conquered the Peloponnesus. Like many other cities of Greece, Megara was formed out of five villages, which were united on one political foundation; and this event must have taken place not later than the middle of the 8th century. From this time for two centuries Megara was among the most powerful cities of Greece. Though it had a harbour called Pegæ on the Corinthian Gulf, and founded a Sicilian colony, Megara Hyblæa, in 728 B.C., yet it did not long compete with Corinth and Corcyra for the western trade. Nisæa on the Saronic Gulf was a better harbour, and gave the Megarians a stronger footing on the eastern seas. In order to keep their hold on the Black Sea traffic, they founded numerous trading stations alongside of their chief rivals, the people of Miletus: Chalcodon and Byzantium on the Bosphorus, and Astacus and Heraclea in Bithynia were colonies of Megara. Wealth and culture increased in the city; the country festivals were celebrated in a more elaborate and orderly manner, and Susarion of Tripodiscus first gave literary form to Grecian comedy, which was soon transferred to Attica.

The situation of Megaris on the isthmus gave it great political power, inasmuch as it commanded all the roads from the Peloponnesus into continental Greece; and so long as the people continued united under an orderly government they maintained their high position. But the development of education prompted the lower classes to demand from the nobles an equal share in the government, and Megara did not, like Athens and Sparta, produce a constitution which could reconcile the contending parties. A tyrant Theagenes raised himself to supreme power as the leader of the popular party; he made an aqueduct for the city, and appears to have maintained its power and splendour. But he was expelled by the nobles about 600 B.C., and for many years Megara was the scene of continual struggles. The poor, who were indebted to the rich, refused to pay what they counted exorbitant interest, and plundered the houses of the nobles. A vivid picture of the state of the city in the 6th century B.C. is preserved in the writings of the poet Theognis, who belonged to the aristocratic party. Meanwhile Athens was rising to power, and maintained a long war with Megara for the island of Salamis. The Megarians gradually lost strength, and finally Solon wrested the island from them for ever. They sent three thousand troops to fight at Plataea. In the wars between Athens and Sparta they were impelled by jealousy of their neighbours of Corinth to join the Athenian alliance, 455–45; but they soon found that they were only the subjects of Athens, and finally

<sup>1</sup> As we have seen, it was mentioned in 1726 by Valentyn, and a young example was in 1830 described and figured by Quoy and Gaimard (*Voy. de l'Astrolabe: Oiseaux*, p. 239, pl. 25) as the *Megapodius rubripes* of Temminck, a wholly different bird.

enrolled themselves among the allies of Sparta. They suffered terribly during the Peloponnesian War: Athenian ships blockaded their harbours and Athenian armies ravaged their land once or twice every year. The long famine in the city is referred to by Aristophanes in the *Acharnians*. The city maintained a flourishing existence throughout the Greek and Roman periods, but played a very subordinate part in history. In the unsettled time when the Roman empire had decayed, it was often plundered by pirates.

As regards literature, Megara's chief distinction, besides the poems of Theognis and the comedy of Susarion, was the school of philosophy founded there by Euclid, a disciple of Socrates. The coinage of the city is a very confused and difficult subject; no very early coins can be with certainty attributed to it. The usual types are Apolline. The topography is described by Pausanias, bk. i. Megara is about four hours' carriage-drive from Athens.

MEGATHERIUM is the name given by Cuvier to a large extinct animal belonging to the order *Edentata* (see *MAMMALIA*, p. 384). A nearly complete skeleton, found on the banks of the river Luxan, near Buenos Ayres, and sent in 1789 to the Royal Museum at Madrid, long

of Desmarest, and are all from the newest or post-Tertiary geological formations of the Argentine Republic and Paraguay, or the lands forming the basin of the Rio de la Plata. Dr Leidy has described, from similar formations in Georgia and South Carolina, bones of a closely allied species, about one-fourth smaller, which he has named *M. mirabile*. A third species, *M. laurillardi* of Lund, is founded upon remains found in Brazil.

The following description will apply especially to the best-known South American form, *Megatherium americanum*. In size it exceeded any existing land animal except the elephant, to which it was inferior only in consequence of the comparative shortness of its limbs, for in length and bulk of body it was its equal, if not superior. The full length of a mounted skeleton from the fore part of the head to the end of the tail is 18 feet, of which the tail occupies 5 feet. The head, which is small for the size of the animal, presents a general resemblance to that of the Sloth; the anterior part of the mouth is, however, more elongated, and the malar bone, though branched posteriorly in the same way as that of the Sloth, meets the zygomatic process of the squamosal, completing the arch. The lower

jaw has the middle part of its horizontal ramus curiously deepened, so as to admit of implantation of the very long-rooted teeth. In number the teeth exactly resemble those of the Sloths, being five above and four below on each side, and they are limited to the lateral parts of the mouth, front teeth being entirely wanting. They resemble those of the Sloths also in their persistent growth, and in their composition of three tissues—vaso-dentine, true dentine, and cement; but they are of prismatic or quadrate form, and the constituent materials of different densities are so arranged that, as they wear, two transverse ridges of hard dentine remain at a greater elevation than the rest of the tooth, producing a very efficient

Skeleton of the Megatherium, from the specimen in the Museum of the Royal College of Surgeons of England.  $\times \frac{1}{12}$ .

remained the principal if not the only source of information with regard to the species to which it belonged, and furnished the materials for many descriptions, notably that of Cuvier, who determined its affinities with the Sloths.<sup>1</sup> In 1832 an important collection of bones of the Megatherium were discovered near the Rio Salado, and were secured for the museum of the College of Surgeons of England, and these, with another collection found at Luxan in 1837, and now in the British Museum, supplied the materials for the complete description of the skeleton published by Professor Owen in 1861. Other skeletons have subsequently been received by several of the Continental museums, as Milan and Paris, and, consequently, our knowledge of the organization of the Megatherium, so far as it can be deduced from the bones and teeth, is as complete as that of any other animal, recent or extinct.

The remains hitherto spoken of are all referred to one species, *Megatherium americanum* of Blumenbach, *M. cuvieri*

tritulating apparatus (see figs. 35 and 36, article *MAMMALIA*, p. 385). The vertebral column consists of seven cervical, sixteen dorsal, three lumbar, five sacral, and eighteen caudal vertebrae. The spinous processes are much better developed than in the Sloths, and are all directed backwards, there being no reversing of the inclination near the posterior end of the dorsal series, as in most active-bodied mammals. In the lumbar region, the accessory zygapophyses, rudimentary in Sloths, are fully developed, as in the Anteaters.

The tail is large, and its basal vertebrae have strong lateral and spinous processes and chevron bones, indicating great muscular development. The scapula resembles that of the Sloths in the union of the acromion with the coracoid, and in the bridging over of the supra-scapular notch. The clavicle is complete and very large much resembling that of man on a large scale. The fore limbs are longer than the hind limbs. The radius and ulna are both well-developed, and have a considerable amount of freedom of movement. The hand is singularly modified. The first digit is represented only by a rudimentary metacarpal, but the next three are large, and terminate in phalanges.

<sup>1</sup> An excellent figure of this skeleton, which unfortunately was incorrectly articulated, and wanted the greater part of the tail, was published by Pander and D'Alton in 1821, and has been frequently reproduced in subsequent works.

adapted for the support of immense claws, the middle one being especially large. The outer or fifth digit has no claw, and it may be considered as certain that the weight of the foot was, in standing and walking, chiefly thrown upon this, and that it was protected by a callous pad below as in the existing great Anteater, while the other toes were curved inwards towards the palm, only coming in contact with the ground by their outer surfaces. The mechanical arrangements by which the weight of the body was thrown entirely upon the outer side of the foot are very curious, and are fully described in Professor Owen's memoir. The pelvis is remarkably wide, even more so than that of the Elephant, but it is formed on the same principle as in the Sloths. The femur is extremely broad and flattened; the tibia and fibula are short and strong, and united together at each end. The hind foot, contrary to the usual rule in the *Edentata*, is even more singularly modified than the hand. The ankle-joint is formed upon a peculiar plan, quite unlike that of the Sloths, or of any other mammal, except the Megatherium's nearest allies. The calcaneum projects nearly as far backwards as the fore part of the foot does forwards. There is no trace of great toe or hallux, or of its corresponding cuneiform bone. The second toe is rudimentary. The third has an enormous ungual phalanx, which, like those of the hand, is remarkable for the immense development of the bony sheath which is reflected from its proximal end around the base of the claw. The two outer toes have large and very peculiarly-shaped metatarsals, but only small phalanges, and no claws. The creature probably walked upon the outer edge of the sole, so that the great falcate claw of the third toe did not come into contact with the ground, and so was kept in a state of sharpness ready for use. The foot was therefore formed upon quite a different principle from that of the Anteaters or Sloths, though somewhat like the latter in having two of the toes aborted.

Taking all the various points of its structure together, they clearly indicate affinities both with the existing Sloths and with the Anteaters, the skull and teeth more resembling those of the former, and the vertebral column and limbs the latter. It is also not difficult to infer the food and habits of this enormous creature. That it was a leaf-eater there can be little doubt, but the greater size and more complex structure of its teeth might have enabled it to crush the smaller branches as well as the leaves and succulent shoots which form the food of the existing Sloths. It is, however, very improbable that it climbed into the branches of the trees like its diminutive congeners, but it is far more likely that it obtained its subsistence by tearing them down with the great hook-like claws of its powerful prehensile fore limbs, being easily enabled to reach them by raising itself up upon the massive tripod formed by the two hind feet, firmly fixed to the ground by the one huge falcate claw, and the stout, muscular tail. The whole conformation of the hinder part of the animal is strongly suggestive of such an action. There can also be little doubt but that all its movements were as slow and deliberate as those of its modern representatives.

An idea at one time prevailed that the Megatherium was covered externally with a coat of bony armour like that of the Armadillos, but this originated in dermal plates belonging to the Glyptodon, a totally distinct animal, having been accidentally associated with bones of the Megatherium. Similar plates, on a smaller scale, have indeed been found in connexion with the skeleton of both *Mylodon* and *Scelidotherium*, animals of the same family, but never yet with the Megatherium, which we may therefore imagine with a covering of coarse hair like that of its nearest living allies, the Sloths and Anteaters.

MEGHNA, a river of India, forming, in the lower part of its course, the great estuary of the Bengal delta, which conveys to the sea the main body of the waters of the Ganges and the Brahmaputra, which unite at Goalánda in Faridpur district. The united waters thence roll south—a mighty river of great depth and turbidness, sometimes split up into half a dozen channels by sand-banks of its own formation, sometimes spreading out into a widespread sheet of water which the eye cannot see across. The river enters the sea by four principal mouths, enclosing the three large islands of Dakshin Sháhazpur, Hatia, and Sandwíp. It is navigable by native boats of the largest burden, and also by river steamers, all the year through; but the navigation is difficult, and sometimes dangerous, on account of shifting sand-banks and "snags," and boisterous weather when the monsoon is blowing. The most favourable season for navigation is between November and February. Alluvion and diluvion are constantly taking place, especially along the seaboard, and in Noákháli district the land is said to have advanced seawards 4 miles in twenty-three years; while the islands fringing the mouth are annually being cut away and redeposited in fresh shapes.

The tidal phenomena of the Meghna surpass those of any other Indian river. The regular rise of the tide is from 10 to 18 feet, and at springs the sea rushes up in a single wave, known as the "bore,"—on the Meghna a justly dreaded danger to boatmen. It is greatest at the time of the biennial equinoxes, when navigation is sometimes impeded for days together. The tidal wave is suddenly beheld advancing like a wall topped with foam of the height of nearly 20 feet, and at the rate of 15 miles an hour; in a few minutes all is over, and the river has changed from ebb to flood tide. A still greater danger is the "storm wave," which occasionally sweeps up the Meghna in the shape of cyclones. The latest and most destructive of these disasters were those of May 1867 and October 1876, when the whole islands and sea-face of the mainland were entirely submerged. In the latter calamity it has been officially estimated that about 19 per cent. of the population in the mainland portion of Noákháli, and in the islands of Sandwíp and Hatia, were drowned, and that a like proportion subsequently died of cholera and other diseases caused by the results of the storm.

MEHÁDIA, a market-town in the county of Szörény, Hungary, is situated on the Bella-Reka, or Bereka, 13½ miles north of Orsova, in 44° 55' N. lat., 22° 22' E. long. The town is small but thriving, and contains Greek Orthodox and Roman Catholic churches, the ruins of a castle, and some interesting Roman antiquities. Mehádia is, however, chiefly of importance as the station for the Hercules Baths, distant about 3 miles east from the town, and situated in a narrow pass in the romantic valley of the Cserna. Of the twenty-two hot springs of Mehádia, nine are now in use, the most powerful one being the Hercules, which yields about 5000 cubic feet of water per hour. The springs are all strongly impregnated with salts of sulphur, iodine, bromine, and chlorine, and their average temperature is 70° to 145° Fahr. They are much used for chronic rheumatism, gout, and cutaneous eruptions, and, during the season, which usually lasts from the middle of

May to the end of September, are resorted to by over a thousand visitors. The town of Mehádía has about 2200 inhabitants, principally Roumanians and Germans.

Already in the times of the Romans famous for their healing efficacy, the *Thermæ Herculis* (*Fontes Herculis*, *Aquæ Herculis*) were the resort of emperors, generals, and senators, whose sojourn there is attested by various inscriptions and relics. The town is the site of the ancient Roman colony of *Ad Mediam*, near which the Roman road from the Danube to Dacia passed in its course through the valley of the Oserna. Subsequent to the destruction of the Roman empire the baths fell into disuse until 1735; great improvements have been effected in them during the present century, and recently a spacious kursaal has been built at the expense of the Hungarian Government. The fortress of Mehádía was often stormed during the wars with the Turks, and notably in 1716, 1738, and 1789.

MEHEMET ALI, or MOHAMMED 'ALÍ. See EGYPT, vol. vii. p. 760 sq.

MÉHUL, ÉTIENNE HENRI (1763–1817), one of the most remarkable composers of France, was born at Givet, in Ardennes, on the 24th of June 1763. His father being too poor to give him a regular musical education, his first ideas of art were derived from a poor blind organist of Givet; yet such was his aptitude that, when ten years old, he was appointed organist of the convent of the Récollets. In 1775 an able German musician and organist, Wilhelm Hauser, was engaged for the monastery of Laval Dieu, a few miles from Givet, and Méhul became his occasional pupil. In his sixteenth year he was taken to Paris by a military officer, and placed himself under Edelmann, a good musician and harpsichord player. His first attempts at instrumental composition in 1781 did not succeed, and he therefore turned his attention to sacred and dramatic music. The great composer Gluck received him kindly, and gave him advice in his studies. After various delays and disappointments during his efforts for six years to obtain, at the Grand Opera, a representation of his *Cora et Alonzo*, he offered to the Opéra Comique his *Euphrosine et Coradin*, which, being accepted and performed in 1790, at once fixed his reputation. The critics acknowledged in it great energy of dramatic expression, and much brilliant instrumentation, but objected to a general want of graceful melody,—a strange complaint, since his style is far more refined than that of either Hérold or Auber. His opera of *Stratonice* had great success. After several other operas which did not succeed, his *Adrien* appeared, and added much to his fame, which was still further increased by his three best works, *Le jeune Henri*, *Uthal*, and *Joseph*, the finest of the series. He had been appointed one of the four inspectors of the Paris Conservatory, but that office made him feel continually the insufficiency of his early studies, a want which he endeavoured to remedy by incessant application. *Timoléon*, *Ariodant*, and *Bion* followed *Stratonice*, with various success. *Uthal* can scarcely be expected to live, since, by desire of Napoleon Bonaparte, it was written for an orchestra without violins. *Epicure* was composed by Méhul and Cherubini jointly; but the superiority of the latter was evident. Méhul's next opera, *L'Irato*, failed. After writing forty-two operas, besides a number of songs for the festivals of the republic, cantatas, and orchestral pieces of various kinds, his health gave way, from an affection of the chest, which terminated his life on the 18th of October 1817.

MEIBOM, HEINRICH (1555–1625), was born at Lemgo on December 4, 1555, and died on September 20, 1625, at Helmstädt, where he had held the chair of history and poetry from 1583. He was a writer of Latin verses (*Parodiarum Horatianarum Libri III. et Sylvarum Libri II.*, 1588), and his talents in this direction were recognized by the emperor Rudolph II, who ennobled him and made him poet laureate in 1590; but his claim to be remembered rests entirely on his services in elucidating the mediæval

history of Germany. His *Opuscula Historica ad res Germanicas spectantia* were edited and published in 1660 by his grandson, Heinrich Meibom (1638–1700), who also was professor of history and poetry at Helmstädt, and incorporated the grandfather's work with his own *Rerum Germanicarum Scriptores* (1688).

MEININGEN, the capital of the little duchy of Saxe-Meiningen, in central Germany, and the seat of the provincial courts for Saxe-Meiningen, Saxe-Coburg, and the Prussian districts of Schmalkalden and Schleusingen, is situated on the right bank of the Werra, about 40 miles to the south of Eisenach. It consists of an old town and several handsome suburbs, but much of the former has been rebuilt in a modern style since a destructive fire in 1874. The chief buildings are the Elisabethenburg, or old ducal palace, dating chiefly from 1682, and containing several collections; the new palace; the new town-house; the post-office; the barracks; and the old town church, with its two towers, erected in 1003. The theatre has lately attained a European reputation for its admirably drilled actors and unexcelled scenic effects. The English Garden, a beautiful public park, contains the ducal mortuary chapel and several monuments. The industries, consisting of brewing and the weaving of woollen and cotton cloth, are insignificant. The population in 1880 was 11,227.

Meiningen, which was subject to the bishops of Würzburg for upwards of 500 years (1000–1542), came into the possession of the dukes of Saxony in 1583. At the partition of 1660 it fell to the share of Saxe-Altenburg, and in 1680 it became the capital of Saxe-Meiningen.

MEISSEN, an ancient and important industrial town of Saxony is situated on the left bank of the Elbe, between the streams Meisse and Triebisch, in the district and about 9 miles to the north-west of the town of Dresden. Its irregular hilly site and numerous fine old buildings give it a quaint and picturesque appearance, and most of the streets are narrow and uneven. The cathedral, one of the finest Early Gothic edifices in Germany, is conspicuously situated on the Schlossberg, 160 feet above the town. It is said to have been originally founded by the emperor Otho I., but the present building was begun in the 13th century, and completed soon after 1400. The lofty tower dates from the 15th century. Within the cathedral are the tombs of several Saxon princes of the 15th and 16th centuries, including those of Albert and Ernest, the founders of the present reigning lines. Adjoining the cathedral stands the castle, dating originally from 1473–81, but restored and named Albrechtsburg in 1676. Another thorough restoration was undertaken in 1863, when a series of historical frescos by celebrated modern artists was begun upon its walls. An old stone bridge of the 13th century connects the Schlossberg with the Ahraberg, which owes its name to the old convent of St Afra. The convent was suppressed by Duke Maurice in 1543, and converted into the "Fürstenschule," one of the most renowned schools in Germany, counting Lessing and Gellert among its former pupils. The other chief buildings are the town-house, built in 1479, and restored in 1875; the fine old town church, also called the Frauenkirche or Marienkirche; and the churches of St Francis, St Nicholas (coeval with the town), and St Afra. Since 1710, immediately after Böttcher's great discovery, Meissen has been the seat of the manufacture of the so-called Dresden china. Till 1863 the porcelain factory was in the Albrechtsburg, but in that year it was transferred to a large new building in the Triebischthal, close to the town, where about six hundred and seventy hands are now employed. Meissen also contains iron foundries, manufactories of earthenware stoves and pottery, a jute-mill, sugar-refineries, breweries,

tanneries, &c. A considerable trade is carried on in the wine produced in the surrounding vineyards. The population in 1880 was 14,166.

Meissen, one of the oldest and most interesting towns in Saxony, was founded by the emperor Henry I. in 928 as an outpost against the Wends, and became the capital of a margraviate, which was afterwards merged in the duchy of Saxony. Its margraves were among the most powerful mediæval princes in Germany, and were the direct ancestors of the present royal house of Saxony. From 965 till 1581 Meissen was also the seat of an important line of bishops, who ranked as princes of the empire. The town suffered greatly from the Hussites in the 15th century, and it was captured by the imperial troops in the war of the Smalkaldian League, and again in the Thirty Years' War. In 1687 it was severely handled by the Swedes, and in 1745 it fell into the hands of the Prussians.

See *Die Stadt Meissen und ihre Umgegend*, 1855; and H. Herbst's *Praktischer Wegweiser durch die Stadt Meissen*, 1878.

MEKONG, MEKHONG, or MAKONG, less frequently NAM-KONG, the Da-Kio of the Tibetans, the Lantsang-Kiang or Lankiang of the Chinese, and the Son-Kong of the Anamese, sometimes also called the Cambodia or Camboja, is one of the largest and most remarkable rivers of southern Asia. As it rises in Tibet, probably about 34° N. lat. and 94° E. long., and reaches the China Sea about 10° N. lat., after a somewhat devious course through Yunnan, Burmah, Siam, Cambodia, and Cochin-China, its total course may be safely stated at 2000 miles. In spite, however, of this great length, the Mekong must be regarded as little more than a mountain torrent on an unusually large scale. It certainly forms a very extensive delta (see COCHIN-CHINA, vol. vi. pp. 93, 94), and is navigable for steamboats as far up as Cratieh (about 280 miles from the river mouth), but navigation soon becomes difficult, not through want of water, but from the great irregularity of the bed. At Stung-Streng the river measures about 2 leagues from bank to bank, and its current is strong even to violence; it "twists into the sharpest eddies, and drives against the banks with fury." A little higher up are the great cataracts of Kong. Beyond these the channel again becomes navigable as far as Bassac, when it is still about 6500 feet in width; but before long the banks close in and the river, narrowed to about 900 feet, pours along a current of extraordinary depth. Above Khemarat the rapids again begin. At Paklay, Mouhot describes the Mekong as larger than the Menam at Bangkok, forcing its way between the lofty mountains with a noise like the roaring of the sea. About 130 miles farther up, at Luang-Prabang, it has again an unobstructed channel about 3000 feet wide; above Sien-kong the river winds through a magnificent plain; but soon afterwards, in spite of its volume of water, it becomes less navigable than before. The great French expedition of 1866-67 touched its course only at one place higher up, Sien-hong; but other travellers have crossed it at various points in Yunnan. Mr Grosvenor found it, near Yung-feng-chang, at a height of 4700 feet above the sea, a stream of from 60 to 80 yards wide, flowing smoothly and steadily in the floor of a deep gorge (see Coleborne Baker, "Trav. and Res. in Western China," *Roy. Geog. Soc. Suppl. Papers*, 1882). It is there crossed by an iron suspension bridge, of Chinese workmanship, consisting of twelve chains with links about 1 foot long (see Gill, *River of Golden Sand*, vol. ii. p. 330). Higher up, near Tse-ku mission-station, lies the terrific defile to which Cooper (*Trav. of a Pioneer of Commerce*, 1871) gave the name of Hogg's Gorge. The head waters of the Mekong have never been traced to their source; but Huc and Gabet saw the confluence of the two main branches at Tsiampo (32° N. lat.), and the abbé Desgodins has followed the stream from that point down to Ye-tche in 27° 20' N. lat. (see *La Mission du Tibet*, Paris, 1872, and the abbé's papers in *Bull. Soc. Géog.*, 1871, 1875, 1876, and 1877). At Yerkalo he observed a curious phenomenon: a

number of wells from 12 to 24 feet deep were sunk down among the granite pebbles which form the bed of the river, just above mean-water mark; and they all yielded water with a greater or less degree of saltiness and warmth. They are covered when the river is in full flood. The river basin in all the upper section is extremely narrow, being separated by long lines of high mountains from the valley of the Salwin on the west and from that of the Chin-sha-kiang or River of Golden Sands on the east. Not till the comparatively low country of Siam is reached are there any affluents of considerable size. The most important are the Se-mún and the Udong on the right, and the Attopen or Se-Kong on the left. The Se-mún or Ubon river was explored as far as Korat by the Lagrée expedition, and its tributary the Se-dóm has been followed by Dr Harmand (*Bull. Soc. Géog.*, 1877). Both streams have a rapid and interrupted course. Like the Nile, the Mekong is subject to a great annual inundation, described as early as the 16th century by Camoens, who calls the river Mecom. At some places the difference between flood-mark and ordinary level is from 35 to 40 feet (see COCHIN-CHINA). The first Europeans to make true acquaintance with the river course were the Dutchman Wusthoff and his fellow ambassadors, who in 1641 ascended as far as Winkyan, i.e., Vienchang; their narrative is given by Valentijn, and might have been enough to suggest that the Mekong could not form a trade route to the interior. For the French exploration which finally settled the question, see Garnier's *Expédition*, &c., 1873, and the notice of Garnier in vol. x. p. 82.

MELA, POMPONIUS, a Roman writer on geography. His little work, though a mere compendium, is the only systematic treatise on the subject preserved to us in the Latin language, with the exception of that which forms part of the encyclopædic work of the elder Pliny, and from this circumstance it derives a value to which it would be little entitled from its intrinsic merits. Nothing is known of the author except his name, and that he was born, as he himself informs us, at a small town called Tingentera in the south of Spain. But the date of his work may be fixed with little doubt from an allusion in the preface to a proposed expedition of the reigning emperor to Britain, which can hardly be referred to any other event than the visit to that island of the emperor Claudius in 43 A.D. This conclusion is accepted by all the recent editors; the view of some earlier scholars, who understood this passage as referring to the expedition of Julius Cæsar, is clearly disproved by the mention of several facts which were not anterior to the reign of Augustus. The little treatise is not only a mere abridgment, occupying less than one hundred pages of ordinary print, but is so deficient in method and systematic character that we should have supposed it to be little more than a mere schoolbook, were it not that we find the name of the author figuring in a prominent manner among the authorities cited by Pliny for the geographical books of his vast compilation.

His general views of the geography of the earth do not differ materially from those which were current among Greek writers from the time of Eratosthenes to that of Strabo, and are well known to us from the great work of the latter author, which was, however, in all probability unknown to Mela, as it certainly was to Pliny. But in one of his views he stands alone among ancient writers on geography, that after describing the division of the earth into five zones, of which two only were inhabitable, he states as an undoubted fact the existence of *antichthones*, who inhabited the southern temperate zone, but were inaccessible and consequently unknown to the inhabitants of the corresponding zone in the north, on account of the excessive heat of the intervening torrid zone. His views

of the division and boundaries of the three continents of Europe, Asia, and Africa coincide with those of Eratosthenes; and, in common with all ancient geographers from the time of Alexander to that of Ptolemy, he regarded the Caspian Sea as an inlet from the Northern Ocean, corresponding to the Persian Gulf on the south. His ideas concerning India are extremely confused and imperfect,—altogether inferior to those possessed by Greek writers long before; he follows Eratosthenes in supposing that country to occupy the south-eastern angle of Asia, whence the coast trended northwards to Scythia, and then swept round to the westward to the opening of the Caspian Sea. As usual he places the Rhipæan Mountains and the Hyperboreans near the Scythian Ocean, which he of course connects with that supposed to exist to the north of Europe.

With regard to the west of Europe, on the other hand, his knowledge was somewhat in advance of the Greek geographers, as might be expected from the extension of the Roman dominion and civilization in that quarter, and from a writer who was himself a native of Spain. Accordingly we find him possessing a more accurate idea than either Eratosthenes or Strabo of the western coast-line of Spain and Gaul, and its deep indentation by a gulf (the Bay of Biscay) between the projecting headlands of the two countries. Of Britain, on the contrary, he has little to tell us, beyond what we find in Cæsar or Strabo, though he appears to have had a clearer idea of the position of the British Islands than the Greek geographer. He is also the first ancient writer who mentions the name of the Orcades or Orkneys, which he correctly describes as a large group of islands to the north of Britain. Of the north of Europe his knowledge was still utterly imperfect; but he had a vague notion of the existence to the north of Germany of a large bay, which he calls Codanus Sinus, containing many islands, large and small, among which was one much larger than the rest, which he calls Codanovia,—evidently the same name that reappears in Pliny under the form Scandinavia, which has been attached by modern writers to the great northern peninsula of Europe.

The method followed by Mela in describing the three continents is peculiar and inconvenient. Instead of treating each continent separately, and describing the countries included in it, he begins at the Strait of the Columns (the Straits of Gibraltar), which was close to his own birthplace, and describes the countries adjoining the south coast of the Mediterranean from Mauretania to Egypt, and afterwards those around the east coast of the same sea with its tributary the Euxine, and then back along the north of the Mediterranean from Scythia to Gaul and Spain. He then begins again with the countries bordering the western and northern ocean from Spain and Gaul round to India, and from thence by Persia and Arabia to the Ethiopians, and thence again round Africa to the straits from which he began. In common with most ancient geographers, he considered Africa as surrounded by the sea, but had a very inadequate idea of its extent towards the south.

The first edition of Pomponius Mela was published in 1471, and it was very often reprinted in the 15th and 16th centuries. The edition of Voss in 1658, with a valuable commentary, became the foundation of all the subsequent editions, of which those by Gronovius (in 1685 and 1742) are among the best-known and most useful. The edition by Tzschucke, in 6 vols. 8vo (1806), contains an overwhelming mass of notes and commentaries, but by far the best text is that of the recent edition by G. Parthey (Berlin, 1867), who has in many instances restored the original readings, which had been displaced by the conjectures of Voss and others. (E. H. B.)

**MELANCHTHON, PHILIP** (1497–1560), was born at Bretten, a town of the lower Palatinate, on February 16, 1497. His father, George Schwartzerd, was a kinsman of the famous Reuchlin, and by profession an armourer or commissary of artillery under the Palatinate princes. His mother, Barbara Reuter, was a thrifty housewife and

affectionate parent, whose pious character is evidenced by a well-known German rhyme, of which she is the reputed author, beginning *Almosen geben armet nicht*. His mother's father, John Reuter, who was for many years mayor of Bretten, charged himself with the education of Philip. Taught first by John Hungarus, then by George Simler at the academy of Pfortzheim, where he lived in the house of Reuchlin's sister, young Schwartzerd exhibited remarkable precocity, and speedily won the regard of Reuchlin, who dubbed him Melanchthon (the Greek form of Schwartzerd), according to the fashion of that age. He lived two years at Heidelberg, and the next three at Reuchlin's university of Tübingen, where he studied law, medicine, and theology, taking his doctor's degree in 1514. He began soon after to give public lectures on rhetoric, and to comment on Virgil and Terence, and ere long it became known among European scholars that a new brilliant star of learning had risen on the horizon, Erasmus prophesying that he would himself be speedily eclipsed. In 1518, on Reuchlin's recommendation, Melanchthon was appointed by the elector of Saxony professor of Greek in the university of Wittenberg. This appointment marked an epoch in German university education; Wittenberg became the school of the nation; the scholastic methods of instruction were summarily set aside, and in a *Discourse on Reforming the Studies of Youth* Melanchthon gave proof, not only that he had thoroughly caught the Renaissance spirit, but that he was fitted to become one of its foremost leaders. He began to lecture on Homer and the Epistle to Titus, and in connexion with the former he announced that, like Solomon, he sought Tyrian brass and gems for the adornment of God's temple. Luther himself received a fresh impulse towards the study of Greek, and his translation of the Scriptures, begun as early as 1517, now made rapid progress, Melanchthon helping to collate the Greek versions and revising Luther's translation. Melanchthon on his part felt the spell of Luther's large personality and spiritual depth, and he seems to have been prepared on his first arrival at Wittenberg to accept the new theology, which indeed as yet existed mainly in subjective form, and as a living spiritual force, in the person of Luther. To reduce it to an objective system, to exhibit it dialectically, the calmer mind of Melanchthon, with its architectural faculty and delicate moral tact, was requisite. Theologically it is impossible to separate Melanchthon from Luther; "the miner's son drew forth the metal, the armourer's son fashioned it." Luther, in whom courage and energy were too much akin to violence and zealous decision to narrow intolerance, and Melanchthon, whose calm deliberation was apt to degenerate into vacillation and whose conciliatory temperament was too much allied to timidity, were each the fit complement of the other.

Melanchthon was first drawn into the arena of the Reformation controversy through the Leipsic discussion, of which he was an eager spectator. He had been sharply reproved by Dr Eck for giving aid to Carlstadt ("Tace tu, Philippe, ac tua studia cura nec me perturba"), and he was shortly afterwards himself attacked by the blustering Ingolstadt doctor. Melanchthon replied in a brief treatise—a model of Christian moderation—setting forth Luther's first principle of the supreme authority of Scripture in opposition to the patristic writings on which Eck so boastfully relied. His marriage in 1520 to Catherine Krapp of Wittenberg increased his own happiness, and gave a domestic centre to the Reformation. In 1521, during Luther's confinement in the Wartburg, Melanchthon occupied the important position of leader of the Reformation cause at the university. He defended the action of the Augustinian monks when they substituted for the celebration of the mass the sacrament of the supper partaken of by

the people under both kinds; but, on the advent of the Anabaptist enthusiasts of Zwickau, he had a still more difficult part to play. Melanchthon was irresolute. In their attacks upon infant baptism they seemed to him to have hit upon a "weak point"; and in regard to their claim to personal inspiration his position was summed up in his own words, "Luther alone can decide; on the one hand let us beware of quenching the Spirit of God, and on the other of being led astray by the spirit of Satan." In the same year he published his *Loci Communes Rerum Theologicarum*.

After the first diet of Spires (1526), where a precarious peace was patched up for the Reformed faith, Melanchthon was deputed as one of twenty-eight commissioners to visit the Reformed states and regulate the constitution of churches, he having just published a famous treatise called the *Libellus Visitatorius*, a directory for the use of the commissioners. At the Marburg conference (1529) between the German and Swiss Reformers, Luther was pitted against Ecolampadius and Melanchthon against Zwingli in the discussion regarding the real presence in the sacrament. How far the candid conciliatory spirit of Melanchthon was biased by Luther's intolerance is evident from the exaggerated and inaccurate accounts of the conference written by the former to the elector of Saxony. At the diet of Augsburg (1530) Melanchthon was the leading representative of the Reformation. With anxiety and tears he drew up for that diet the seventeen articles of the evangelical faith, which are known as the "Augsburg Confession." He held conferences with Romish divines appointed to adjust differences, and afterwards wrote an *Apology for the Augsburg Confession*. After the Augsburg conference further attempts were made to settle the Reformation controversy by a compromise, and Melanchthon, from his conciliatory spirit and facility of access, appeared to the Romanists the fittest of the Reformers to deal with. His historical instinct led him ever to revert to the original unity of the church, and to regard subsequent Romish errors as excrescences rather than proofs of an essentially anti-Christian system. He was weary of the *rabies theologorum*, and fondly dreamed that the evangelical leaven, if simply tolerated, would at length purify the church's life and doctrine. In 1537, when the Protestant divines signed the Lutheran Articles of Smalkald, Melanchthon appended to his signature the reservation that he would admit of a pope provided he allowed the gospel and did not claim to rule by divine right.

The year after Luther's death, when the battle of Mühlberg (1547) had given a seemingly crushing blow to the Protestant cause, an attempt was made to weld together the iron and clay of the evangelical and the papal doctrines, which resulted in the compilation by Pflug, Sidonius, and Agricola of the Augsburg "Interim." This was proposed to the two parties in Germany as a provisional ground of agreement till the decision of the council of Trent. Melanchthon, on being referred to, declared equivocally that, though the Interim was inadmissible, yet so far as matters of indifference (*adiaphora*) were concerned it might be received. Hence arose that "adiaphoristic" controversy in connexion with which he has been misrepresented as holding among matters of indifference such cardinal doctrines as justification by faith, the number of the sacraments, as well as the dominion of the pope, feast-days, and so on. The fact is that, in these tentative negotiations, Melanchthon sought, not really to minimize differences, but to veil them under an intentional obscurity of expression. Thus he allowed the necessity of good works to salvation, but not in the Romish sense, proposed to allow the seven sacraments, but only as rites which had no inherent efficacy to salvation, and so on. He afterwards retracted

his compliance with the *adiaphora*, and never really swerved from the views set forth in the *Loci Communes*; but he regarded the surrender of more perfect for less perfect forms of truth or of expression as a painful sacrifice rendered to the weakness of erring brethren. Luther, though he had uttered certain expressions of dissatisfaction with Melanchthon, and had more keenly defended in his last years what was distinctively his own, yet maintained hearty and unbroken friendship with him; but after Luther's death certain smaller men arose in name of Luther who formed a party emphasizing the extremest points of the doctrine of the latter. Hence the later years of Melanchthon were much occupied with acrid controversies within the evangelical church; an account of these, however, would be out of place here. His last years were spent in fruitless conferences with his Romanist adversaries, and amid various controversies among the Reformed, but the flame of his piety burnt brightly till the close. He died in his sixty-third year, on the 19th April 1560, and his body was laid beside that of Martin Luther.

Melanchthon's ever ready pen, clear thought, and elegant style made him the scribe of the Reformation, most public documents on that side being drawn up by him. He never attained entire independence of Luther, though he gradually modified some of his positions from those of the pure Lutherism with which he set out. His development is chiefly noteworthy in regard to these two leading points—the relation of the *evangelium* or doctrine of free grace (1) to free will and moral ability, and (2) to the law and *penitentia* or the good works connected with repentance. At first Luther's cardinal doctrine of grace appeared to Melanchthon inconsistent with any view of free will; and, following Luther, he renounced Aristotle and philosophy in general, since "philosophers attribute everything to human power, while the sacred writings represent all moral power as lost by the fall." In the first edition of the *Loci* (1521) he held, to the length of fatalism, the Augustinian doctrine of irresistible grace, working according to God's immutable decrees, and denied freedom of will in matters civil and religious alike. In the Augsburg Confession (1530), which was largely due to him, freedom is claimed for the will in non-religious matters, and in the *Loci* of 1533 he calls the denial of freedom Stoicism, and holds that in justification there is a certain causality, though not worthiness, in the recipient subordinate to the Divine causality. In 1535, combating Laurentius Valla, he did not deny the spiritual incapacity of the will *per se*, but held that this is strengthened by the word of God, to which it can cleave. The will co-operates with the word and the Holy Spirit. Finally, in 1543, he says that the cause of the difference of final destiny among men lies in the different method of treating grace which is possible to believers as to others. Man may pray for help and reject grace. This he calls free will, as the power of laying hold of grace. Melanchthon's doctrine of the three concurrent causes in conversion, viz., the Holy Spirit, the word, and the human will, suggested the semi-Pelagian position called Synergism, which was held by some of his immediate followers.

In regard to the relation of grace to repentance and good works, Luther was disposed to make faith itself the principle of sanctification. Melanchthon, however, for whom ethics possessed a special interest, laid more stress on the law. He began to do this in 1527 in the *Libellus Visitatorius*, which urged pastors to instruct their people in the necessity of repentance, and to bring the threatenings of the law to bear upon men in order to faith. This brought down upon him the opposition of the Antinomian John Agricola. In the *Loci* of 1535 Melanchthon sought to put the fact of the co-existence of justification and good works in the believer on a secure basis by declaring the latter necessary to eternal life, though the believer's destiny thereto is already fully guaranteed in his justification. In the *Loci* of 1543 he did not retain the doctrine of the necessity of good works in order to salvation, and to this he added, in the Leipsic Interim, "that this in no way countenances the error that eternal life is merited by the worthiness of our own works." Melanchthon was led gradually to lay more and more stress upon the law and moral ideas; but the basis of the relation of faith and good works was never clearly brought out by him, and he at length fell back on his original position that we have justification and inheritance of bliss in and by Christ alone, and that good works are necessary by reason of immutable Divine command.

Melanchthon's life has been written by Camerarius. See also Matthes, *Ph. Melanchthon, sein Leben und Wirken*, 1841; Galle, *Charakteristik Melanchthons als Theologen*, Halle, 1845; Rothe's *Gedächtnissrede auf Melanchthon*, 1860; Nitzsch, *Melanchthon*, 1860; Schmidt, *Melanchthons Leben*, 1864. There is a biography in English by F. A. Cox, 2d ed., London, 1817. The works of Melanchthon, including his correspondence, are contained in the voluminous *Corpus Reformatorum*, edited by Bretschneider and Bindseil. (J. W.)

**MELANESIA.** This term comprises that long belt of island groups which, beginning in the Indian archipelago at the east limits of the region there occupied by the Malay race, and, as it were, a prolongation of that great island region, runs south-east for a distance of some 3500 English miles, *i.e.*, from New Guinea at the equator, in 130° E. long., to New Caledonia just within the Tropic, 167° E. long., and eastwards to Fiji, in 180°. This chain of groups has a certain geographical as well as ethnical unity. Its curve follows roughly the outline of the Australian coast, and large islands occur, with a number of small ones, along the whole length, with mountains of considerable height, coinciding pretty closely with a line of volcanic action. Melanesia is usually held to begin with New Guinea, this great island being then viewed as the headquarters of that dark Papuan race which, widely and variously modified in all the other groups, occupies the whole region, as the name Melanesia implies; but the race really extends farther west, for the large islands Flores and Timor, with several smaller ones, are also essentially Papuan.

New Guinea, 1490 miles long, and containing about 303,000 square miles, the largest island in the world after Australia, is clothed with almost impenetrable forests, through which mountain ranges rise to a height of 13,000 feet. Parallel to its longer axis, 150 miles to the north, are the Admiralty Islands, all small, with one exception, in which the hills rise to 1600 feet, and which is probably of volcanic origin, as the natives use spearheads and implements of obsidian. A Polynesian element seems to be present, and customs peculiar to both races have been observed. Mr H. N. Moseley, of the "Challenger," found them shrewd but honest traders, with much artistic skill in their carvings and designs. They have numerals up to 10, with an idiom for 8 and 9, *viz.*, 10-2 and 10-1, which is found also at Yap in the Carolines, and in the Marshall Islands.

Next follow, east, the two large islands of New Britain, about 340 by 23 English miles, with active volcanoes up to 4000 feet, and New Ireland, about 240 by 22 miles. Next comes the Solomon group, 600 English miles in length, with seven large islands from 135 to 90 miles long, all running north-west and south-east, with volcanic peaks up to 8000 feet. The forms more characteristic of the New Guinea fauna do not extend beyond this group. Its forest vegetation is especially luxuriant. Then comes Santa Cruz, a small group partly volcanic, but with numerous coral reef islands. Then the Banks and New Hebrides group, over 500 English miles in length, all volcanic except the Torres reef islands in the north. Several spots in this group are occupied by people of purely Polynesian race, immigrants apparently from the eastward. Two hundred miles south-west from the New Hebrides lies the island of New Caledonia, about 240 by 25 English miles. It is in parts very mountainous, rising to 5380 feet, the rocks being sedimentary and plutonic, but there are no volcanoes. It lies half way between Australia and Fiji, 700 miles from each. Being outside the equatorial belt, it is much drier and more barren than the other groups, and its fauna and flora have many Australian and Polynesian affinities. The small Loyalty chain lies 70 miles east of New Caledonia, and parallel to it. Fiji is detached from the other Melanesian groups, and differs from them in various particulars. It consists of two large and about 300 small islands, the total area being about 7400 square miles.

Of the two great Pacific races—the brown Polynesian, and the dark Melanesian—the former, considering the vast region it occupies, is singularly homogeneous both in appearance and language, whereas in Melanesia even neighbouring tribes differ widely from each other in both respects. Still, all the Melanesians have certain common

characteristics which distinguish them sharply from the other race. They stand at a lower level of civilization, as is well seen at certain spots in Melanesia where isolated Polynesian settlements exist, due probably to involuntary migration, and where the two races, though they have some peculiar customs in common, live in bitter mutual hostility. The Melanesians are mostly "negroid" in appearance, nearly black, with crisp curly hair elaborately dressed; the women hold a much lower position than among the Polynesians; their institutions, social, political, and religious, are simpler, their manners ruder and often indecent; they have few or no traditions; cannibalism, in different degrees, is almost universal; but their artistic skill and taste, as with some of the lower African negroes, are remarkable, and they are amenable to discipline and fair treatment. Their languages, amid considerable differences, which, as between the Melanesian proper and the Papuan, are very wide, have features which mark them off clearly from the Polynesian, notwithstanding certain fundamental relations with the latter.

The various Melanesian groups will be found described in detail under separate headings.

**MELBOURNE**, the capital of the colony of Victoria, and the most populous city in Australia, is situated at the head of the large bay of Port Phillip, on its northern bend known as Hobson's Bay, about 500 miles S.W. of Sydney by land and 770 by sea, the position of the observatory being 37° 49' 53" S. lat. and 144° 58' 42" E. long. Along the shores of the bay the suburbs

Port Phillip and Environs of Melbourne.

extend for a distance of over 10 miles, but the part distinctively known as the "city" occupies a site about 3 miles inland on the north bank of the Yarra river.

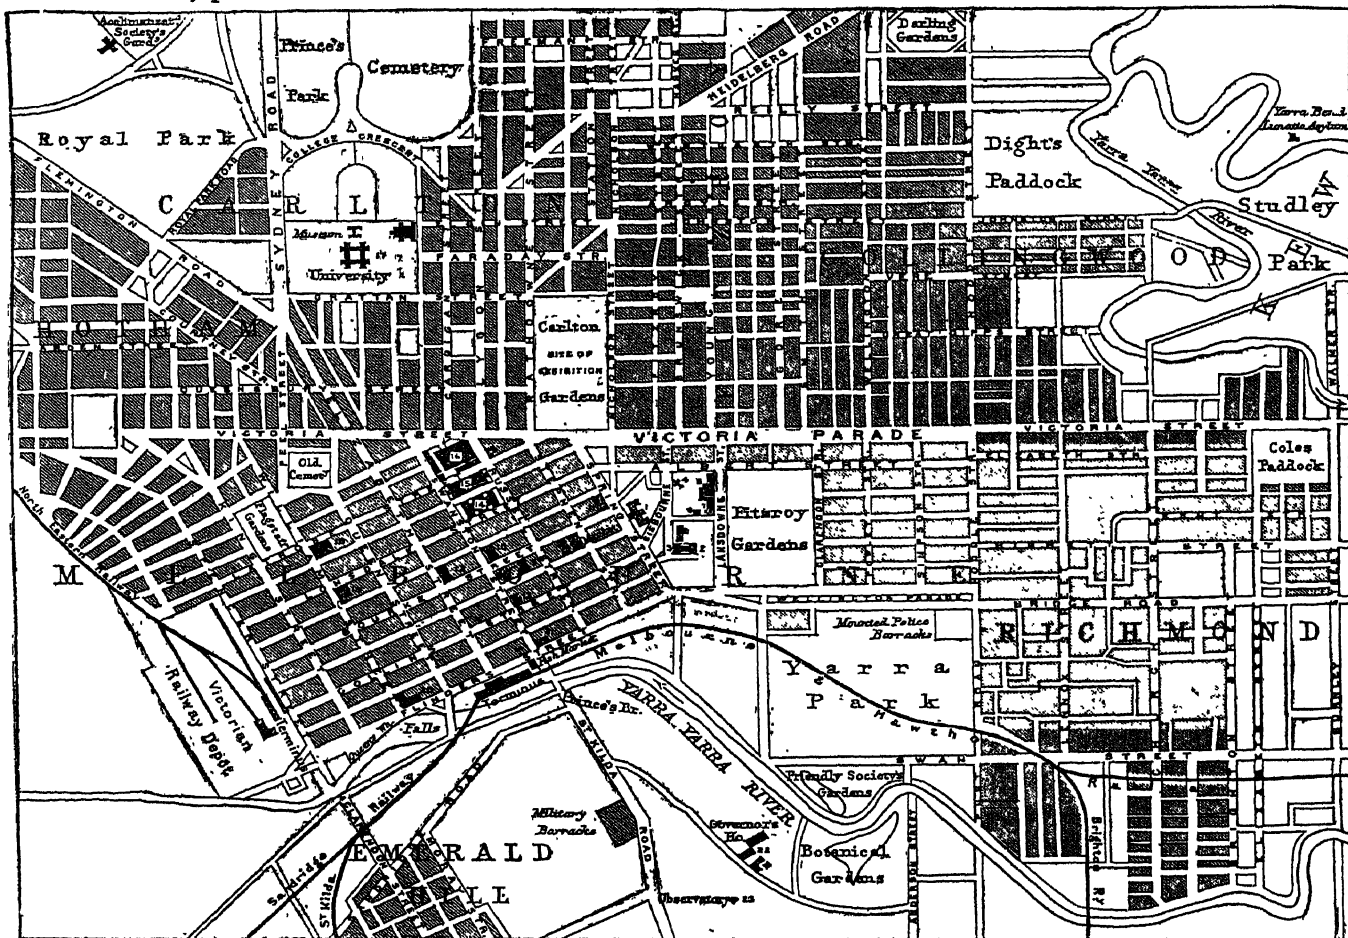

The appearance of Melbourne from the sea is by no means picturesque. The shipping suburbs of Sandridge and Williamstown occupy the alluvial land at the mouth

of the Yarra, and, as the district is low and flat, and covered with factories, the prospect is not inviting. But the city itself has a very different aspect: its situation is relieved by numerous gentle hills, which show off to great advantage its fine public buildings; its streets are wide and well kept; and the universal appearance of prosperity, activity, and comfort under its usually clear blue sky impresses the visitor favourably.

That part specially known as the "city" had a population in 1881 of 65,800. It occupies the two hills of East Melbourne and West Melbourne; the valley that separates them, once occupied by a densely wooded little stream, is now partly filled in, and forms the busy thoroughfare of Elizabeth Street; parallel to this runs Swanston Street,

and at right angles to these, and parallel to the river, are Bourke Street, Collins Street, and Flinders Street,—the first being the busiest in Melbourne, the second containing the most fashionable shops, and the third, which faces the river, being given over to maritime pursuits. These streets are the eighth of a mile apart; between them are narrower streets occupied by warehouses and business premises.

Round the "city" lies a circle of populous suburbs. North-east is Fitzroy with 23,000 inhabitants; farther east, Collingwood, 24,000; east of Melbourne, Richmond, 23,400; south-east, Prahran, 21,000; south, Emerald Hill, 25,300; south-west, Sandridge, 8,700; north-west, Hotham, 17,800. These all lie within three miles of the general

Plan of Melbourne.

post-office in Elizabeth Street; but outside of them, and within a radius of 5 miles, there is a circle of less populous suburbs: to the north, Brunswick, 6200; east, Kew, 4200, and Hawthorn, 6000; south-east, St Kilda, 11,600, and Brighton, 4700; south-west, Williamstown, 9000, and Footscray, 6000; north-west, Essenden and Flemington, 5000. Numerous smaller suburbs fill up the spaces between these,—the principal being Northcote, Preston, Camberwell, Toorak, Caulfield, Elsternwick, and Coburg, with a united population of 19,000.

Fifteen of these suburbs rank as independent municipalities, and many of them have streets which for importance rival the main streets of the city.

The following table shows the growth of the population since 1851:—

|                | 1881.   |         |         | Total   |         |        |
|----------------|---------|---------|---------|---------|---------|--------|
|                | Male.   | Female. | Total.  | 1871.   | 1861.   | 1851.  |
| Melbourne..... | 54,526  | 31,333  | 65,859  | 54,993  |         |        |
| Suburbs.....   | 113,785 | 103,263 | 217,048 | 151,787 |         |        |
| Total.....     | 148,311 | 134,596 | 282,907 | 206,780 | 191,254 | 25,000 |

The land on which the city now stands was sold in allotments of half an acre, the prices realized being in June 1837 about £34 each, in November 1837 about £42, and in September 1838 about £120 each. These allotments are now (1882) sold at prices ranging from £20,000 to £40,000. But, though land has thus increased in value, Melbourne is by no means a crowded city; the streets are all 99 feet wide, and the parks, squares,

and gardens are so numerous that with only one-thirteenth of the population of London it occupies very nearly half as great an area.

The public buildings are generally situated on positions from which they are seen to advantage. The Parliament Houses form a great pile of brickwork with four fronts in freestone, of which the main front is not yet completed; the interior decorations are highly elaborate. The Treasury is a well-proportioned building in freestone; behind it stands a vast building known as the Government offices. On the hill of West Melbourne there is a large structure, newly erected, for the law courts; it has four very handsome fronts, each about 300 feet in length, and the whole is surmounted by a lofty cupola, in the manner of the Capitol at Washington. The public library in Swanston Street forms one of four fronts of a building which was projected on a grand scale, but has never been completed. Much of the interior has been erected, but of the fronts only the main one is yet in existence, its cost having been £111,000. The lower story is devoted to sculpture; on one side there are casts of all the most famous statues; on the other there is a small collection of original works by modern sculptors, together with a gallery containing 8000 engravings and photographs; to the rear is the picture gallery, a very handsome hall, with oil paintings, chosen from the works of living artists. Another of the interior portions of the building is occupied by the technological museum, in which are arranged about 30,000 specimens illustrative of the industrial arts. The upper story of the front is devoted to the library, which occupies a chamber 240 feet long; 22 recesses contain each its own special branch of literature, the total number of volumes being 112,000. The book shelves rise to a height of 20 feet, but they are divided by a narrow gallery which runs all round the room, and gives access to the upper tiers. The library is open to the public; and every visitor ranges at will, being bound by the two conditions only that he is to replace each book where he found it, and that he is to preserve strict silence. During 1881 there were 261,886 visits made to the room.

The Melbourne University is a picturesque, but by no means imposing mass of buildings, buried among the trees of extensive and well-kept grounds about a mile from the heart of the city. In front of it stands the "Wilson Hall," erected at a cost of £40,000. Behind is the National Museum, containing collections of specimens of natural history. The museum, like all public places in Melbourne, is freely open to the people. About 98,000 visitors entered it in 1881. The university has a staff of 10 professors and 12 lecturers, with about 400 students. There are four courses open to students: arts, law, medicine, and civil engineering. Affiliated to the Melbourne University are the two denominational colleges, Trinity and Ormond, in which about 80 students reside, and where provision is made for instruction in theology.

The Exhibition building consists of a nave 500 feet long and 160 feet broad, surmounted by a dome, with two annexes each 460 feet long. These are built in brick with cement facings. The mint is a very handsome quadrangle, erected in 1872. In the year 1881 there were three millions of sovereigns coined in it, making a total of sixteen millions since its erection. The governor's residence is a large building on a hill overlooking the Yarra. The general post-office forms only half of a magnificent pile of buildings which will, when completed, include the central telegraph office.

The town-hall, at the corner of Swanston Street and Collins Street, contains, besides the usual apartments for municipal offices, a hall seated for nearly 3000 persons,

and fitted with a colossal organ, on which the city organist performs two afternoons a week, the public being admitted at a nominal charge. Hotham, Richmond, Emerald Hill, Prahran, and Fitzroy have their own town-halls, all costly and somewhat pretentious buildings.

The markets, erected at a cost of £80,000, stand in Bourke Street. They are handsome in external appearance, and ingeniously contrived for convenience within. The observatory is a humble-looking building on the St Kilda Road; it contains an equatorial telescope, which had for some years the distinction of being the largest in the world.

There are two railway stations, one being the terminus of all the country lines, and the other devoted to suburban traffic. The suburbs of Williamstown, Sandridge, Footscray, St Kilda, Emerald Hill, Brighton, Elsternwick, Hawthorn, Richmond, and Essendon are connected by rail with the city.

The Melbourne Hospital is in the form of an extensive series of brick buildings, situated close to the public library. There are beds for about 300 patients. The Alfred Hospital, on the St Kilda Road, was built in commemoration of the visit of Prince Alfred; it has beds for nearly 100 patients. The lying-in hospital can accommodate 62 persons. The blind asylum has over 100 inmates; and there are a deaf and dumb asylum, an immigrants' home, and other charitable institutions.

Melbourne contains many churches, but few of them will compare with the public buildings in appearance. The Roman Catholic cathedral of St Patrick, when completed, will, however, be a conspicuous ornament to the city. The Anglican cathedral, now (1882) in the course of erection, is to cost about £100,000. The most striking ecclesiastical building is the Scotch church in Collins Street, which divides with Ormond College and the Wilson Hall the honour of being the finest specimen of architecture in the city.

There are in Melbourne, among its numerous state schools, about thirty whose size and proportions entitle them to rank with the architectural ornaments of the city. They have each accommodation for from 600 to 2000 scholars. Abundant provision has been made for secondary instruction by the denominations and by private enterprise. The Scotch College and the Presbyterian Ladies' College, the Wesley College and the Wesleyan Ladies' College, the Church of England Grammar School, St Patrick's College and St Francis Xavier's College, are all connected with the churches; and there are besides between twenty and thirty good private grammar schools.

Melbourne contains the offices of numerous banks, savings banks, and building societies.

The parks and public gardens of Melbourne are extensive and handsome. Within the city proper there are four gardens, which have been decorated with a lavish expenditure. The Fitzroy Gardens are one dense network of avenues of oak, elm, and plane, with a "fern-tree gully" in the middle. Casts of famous statues abound; and ponds, fountains, rustic houses, and small buildings after the design of Greek temples give a variety to the scene. The Treasury, Flagstaff, and Carlton Gardens are of the same class, but less costly in their decorations. Around the central city there lie five great parks. The Royal Park, of about 600 acres, is lightly timbered with the original gum trees; some portions of open land are used for recreation. About 30 acres in the centre are beautifully laid out to accommodate a very superior zoological collection. The Yarra Park, of about 300 acres, contains the leading cricket grounds; of these the "Melbourne" is the chief, distinguished by its very large stand and the excellence of its pitch. The Botanic Gardens occupy

about 200 acres of land, sloping down to the banks of the river, and laid out with great taste and skill. Albert Park, about 500 acres in extent, is not so elaborately laid out, but contains a small lake, which is much used for boating purposes, as the bay is stormy and exposed. Studley Park, a favourite place for picnics, is a romantic corner on a bend of the upper Yarra, of about 200 acres extent, left entirely in a state of nature.

Besides these parks each suburb has its own "gardens" of moderate extent. At Flemington a large reserve is devoted to racing purposes, where in November the race for the Melbourne Cup is held, the great racing carnival of Australia, attended by about 100,000 persons.

The shipping of Melbourne is very considerable. In 1880 about 1500 vessels entered and cleared again, their tonnage being 960,000. Nearly all the intercolonial and a small proportion of the foreign vessels ascend the Yarra and unload in the heart of the city. The river was originally navigable for vessels of only 9 feet draught; but of late years the channel has been deepened so much that vessels drawing 16 feet can ascend with safety. Great works are now in operation by which the course is to be straightened and further deepened; and the quays which line the river banks will be made accessible to the large vessels which now have to lie in the bay off the Sandridge and Williamstown piers.

Shipbuilding is a comparatively unimportant industry, but a great deal of repairing is done; the graving dock at Williamstown is able to hold the largest vessels which enter the port.

The total values of the imports of Melbourne for 1879 and 1880 were respectively £15,035,000 and £14,557,000, and of the exports £12,454,000 and £15,954,000.

In 1881 Melbourne contained 2469 factories, employing 38,141 hands, and converting £8,012,745 worth of raw material into £13,384,836 worth of finished articles. The leading products are leather, flour, clothing, furniture, boots, carriages, preserved meats, ales, soap, candles, cigars, ironwork, jewellery, jams, confectionery, biscuits, and woollens.

The city is abundantly supplied with newspapers, including three morning and three evening dailies. Two reviews are published.

The climate of Melbourne is exceptionally fine, the only drawback being the occasional hot winds which blow from the north for two or three days at a time, and raise the temperature to an uncomfortable extent. But the proportion of days when the sky is clear and the air dry and mild is large. The mean annual temperature is 57°, which would make the climate of Melbourne analogous to that of Madrid, Marseilles, or Verona, but without the extremes experienced in those places. Snow falls every year in Italy, while it is unknown in Melbourne; and the highest temperature reached there in summer is below that of the cities mentioned.

As a field for emigration from European countries, Melbourne offers many advantages to the industrious mechanic or labourer.

The cost of living is about the same as in London. Rents are higher, and furniture and utensils dearer; but butcher meat, bread, and clothes are cheaper.

There is no city where more has been done for the working-classes or where they have made so good a use of their advantages. Many of their efforts at government (for they have all the power in their hands) have been ill-advised, but individually they have exhibited a prudence of which the community reaps the fruits. It is one of the peculiar features of Melbourne that about three out of every four mechanics who have reached middle life own the neat cottages they occupy.

*History.*—The city of Melbourne is without exception the most striking instance of the aptitude of the Anglo-Saxon race for colonization. It was not till the opening years of the present century that the first European sailed through the narrow entrance to Port Phillip, and it was only in 1835 that the white man made his habitation there. In that year John Fawkner sailed up the Yarra in his little vessel the "Enterprise," laden with materials for a settlement; he was stopped by a slight waterfall in a valley where dense groves of wattle trees all in bloom loaded the air with perfume, and where flocks of white cockatoos whirled aloft when the first stroke of the axe resounded in the forest. This spot is now the centre of a great city 10 miles in length, 6 in breadth, covering an area of 45,000 acres, and peopled by 283,000 persons. So rapid and solid a growth, at a distance from the mother country of the whole extent of the earth, is an example of colonizing enterprise altogether without parallel.

The settlement was at first called by the native name "Dootigala," but a desire for distinguished patronage caused the portion on the sea-shore, which was then esteemed the more important, to be called "Williamstown," after King William IV., while the little collection of huts some 3 or 4 miles inland was named "Melbourne," in honour of the prime minister Lord Melbourne.

For two years a constant stream of squatters with their sheep flowed in from Tasmania; then numerous "overlanders" drove their flocks from the Sydney side across the Murray and settled near Port Phillip. Captain Lonsdale was sent by the Sydney Government to act as police magistrate, but in 1838 Mr Latrobe was placed in charge with the title of superintendent. As the squatters prospered Melbourne increased in size, so that in 1841 it contained 11,000 inhabitants. A period of depression occurred in 1843, followed by several years of the greatest prosperity, till, in 1851, gold was discovered in New South Wales. The district of Port Phillip became infected by the excitement; many parties scoured that part of the country in search of the precious metal, and six weeks after the first discovery of it there the great riches of Ballarat were made known. Within a year from that time a hundred thousand men had landed in the colony in order to proceed to the diggings; for several years after the same number landed every twelve months; and Melbourne increased in population from 30,000 to 100,000 in the course of two or three years.

During the year of the gold discoveries, the Port Phillip district was separated from New South Wales, and formed into a separate colony with the name Victoria. In 1855 the British Government granted to it a complete autonomy; Melbourne became the capital of the new colony. (A. SÜ.)

MELBOURNE, WILLIAM LAMB, SECOND VISCOUNT (1779–1848), second son of the first Viscount Melbourne, was born 15th March 1779. After completing his course at Trinity College, Cambridge, he studied law at the university of Glasgow, entered Lincoln's Inn in 1797, and was called to the bar in 1804. In 1805 he married Lady Caroline Ponsonby, daughter of the earl of Bessborough, who after her separation from him acquired some fame as a novelist, and was also a friend of Lord Byron. On entering parliament the same year Lamb joined the opposition under Fox, of whom he was an ardent admirer; but his Liberal tendencies were never of a very decided character, and he not unfrequently gave his support to Lord Liverpool during that statesman's long tenure of office. During the short ministry of Canning in 1827 he was chief secretary for Ireland, but he afterwards for a time adhered to the small remnant of the party who supported the duke of Wellington. The influence of Melbourne as a politician dates from his elevation to the peerage in 1828. Disagreeing with the duke of Wellington on the question of parliamentary reform, he in 1830 entered the ministry of Grey as home secretary. For the discharge of the difficult and multifarious duties of this office at such a critical time he was decidedly deficient both in insight and in energy, but his political success was totally independent of his official capacity; and, when the ministry of Grey was wrecked on the Irish question, Melbourne was chosen to succeed him. Almost immediately he had to give place to a Conservative ministry under Peel, but, the verdict of the country being in his favour, he resumed office in 1835. The period of his ministry was wholly uneventful, and for a considerable time before he resigned in 1841 he had lost the confidence of the

country. From the time of his retirement from office he took little interest in politics. He died at Melbourne House, Derbyshire, 24th November 1848.

Lord Melbourne was without even the elementary qualification of diligent attention to details, which in the absence of higher endowments sometimes confers on a statesman the greater part of his success. Nor can it be said that in public he ever displayed any of those specious and brilliant talents which are often found an acceptable substitute for more solid acquirements. Though he possessed a fine and flexible voice, his manner as a speaker was ineffective, and his speeches were generally ill-arranged and destitute of oratorical point, notwithstanding his occasional indulgence in inelegant flights of rhetoric. Indeed his political advancement was wholly due to his personal popularity. He had a thorough knowledge of the private and indirect motives which influence politicians, and his genial attractive manner, easy temper, and vivacious, if occasionally coarse, wit helped to confer on him a social distinction which for a time led many to take for granted his eminence as a statesman. The most notable and estimable feature of his political conduct is his relation to Queen Victoria, whom he initiated into the duties of sovereign with the most delicate tact and the most friendly and conscientious care.

MELCHIADES, or MELTIADDES (other forms of the name being Meltiades, Melciades, Milciades, and Miltides), was pope from July 2, 310, to January 10 or 11, 314. He appears to have been an African by birth, but of his personal history nothing is known. The toleration edicts of Galerius and of Constantine and Licinius were published during his pontificate, which was also marked by the holding of the Lateran synod in Rome (313), at which Cæcilianus was acquitted of the charges brought against him, and Donatus condemned. Melchiades was preceded and followed by Eusebius and Sylvester I. respectively.

MELCHITES. The name of Melchites (Syriac, *Malkāyē*; Arabic, *Malakīya*, or in the vulgar pronunciation *Milkiya*) means etymologically the royal party, and so is currently applied in the East to Syrian and Egyptian Christians of the Orthodox Greek Church, adherents of the creed supported by the authority of the king, that is, of the Byzantine emperor. The Melchites therefore are those who accept the decrees of Ephesus and Chalcedon as distinguished from the Nestorians and Jacobites, and the name reflects in an interesting manner the way in which the doctrinal controversies that agitated the Eastern empire associated themselves with national feelings of antagonism to the imperial rule.

MELCHIZEDEK (מֶלְכִּי־צֶדֶק, "king of righteousness"), king of Salem and priest of "supreme El" (*El'elyōn*), brought forth bread and wine to Abram, on his return from the expedition against Chedorlaomer, and blessed him in the name of the supreme God, possessor (or maker) of heaven and earth. And Abram gave him tithes of all his booty (Gen. xiv. 18-20). The Bible history tells us nothing more about Melchizedek (comp. Hebrews vii. 3); but the majestic figure of the king-priest, prior to the priesthood of the law, to whom even the father of all Israel paid tithes, suggested a figurative or typical application, first in Psalm cx. to the vicegerent of Jehovah, seated on the throne of Zion, the king of Israel who is also priest after the order of Melchizedek, and then, after the gospel had confirmed the Messianic interpretation of the Psalm (Matt. xxii. 42 sq.), to the kingly priesthood of Jesus, as that idea is worked out at length in the Epistle to the Hebrews.

The theological interest which attaches to the idea of the pre-Aaronic king-priest in these typical applications is practically independent of the historical questions suggested by the narrative of Gen. xiv. It is generally recognized that this chapter holds quite an isolated place in the Pentateuchal history; it is the only passage which presents Abraham in the character of a warrior, and connects him with historical names and political movements, and there are no clear marks by which it can be assigned to any one of the documents of which Genesis is made up. Thus, while one school of interpreters finds in the chapter the earliest fragment of the political history of western Asia, some even holding with Ewald that the narrative is probably based on old Canaanite records, other critics,

as Nöldeke, regard the whole as unhistorical and comparatively late in origin. On the latter view, which finds its main support in the intrinsic difficulties of the narrative, it is scarcely possible to avoid the conclusion that the chapter is one of the latest additions to the Pentateuch (Wellhausen). The historical arguments *pro* and *con* may be seen at length in recent commentaries, but especially in Tuch's essay (*Z. D. M. G.*, i. 161 sq., reprinted in the second edition of his *Genesis*), which was long viewed as decisive in favour of the narrative, and in Nöldeke's *Untersuchungen*, 1869, p. 156 sq., with which compare Wellhausen in *Jahrb. f. D. Th.*, 1876, p. 414 sq. The Assyrian monuments offer no decisive evidence, but are held to confirm the historical possibility of the proper names (Schrader, *KI. und AT.*, p. 46 sq.; Delitzsch, *Paradies*, p. 224). Here we can only speak of the episode of Melchizedek, which, though connected with the main narrative by the epithets given to Jehovah in verse 22, seems to break the natural connexion of verses 17 and 21, and may perhaps have come originally from a separate source. As the narrative now stands Salem must be sought in the vicinity of "the king's dale," which from 1 Sam. xviii. 18 probably but not necessarily lay near Jerusalem. That Salem is Jerusalem, as in Psalm lxxvi. 2, is the ancient and common view, and is necessarily followed by those who view Melchizedek as a late creation. Those who hold the opposite view now lean to the identification with the *Σαλειμ* of John iii. 23, 8 miles south of Bethshean, which Jerome (*Ep.* lxxiii. ad *Evangelium*) confirms by a worthless tradition. In a genuine record of extreme antiquity the union of king and priest in one person, the worship of El as the supreme deity by a Canaanite,<sup>1</sup> and the widespread practice of the consecration of a tithe of booty can present no difficulty; but, if the historical character of the narrative is denied, the origin of the conception must be placed as late as the rise of the temporal authority of the high priests after the exile. An ancient legend identifies Melchizedek with Shem (Palestinian Targum, Jerome on Isa. xli., Ephraem Syrus *in loco*).

MELCOMBE REGIS. See WEYMOUTH.

MELLENDEZ VALDES, JUAN (1754-1817), minor poet of Spain, was born at Ribera del Fresno, Badajoz, on March 11, 1754. He was destined by his parents, who were in good circumstances, for an official career; and accordingly, after having completed his preliminary education at Madrid and Segovia, he went to Salamanca, and duly graduated in laws. At an early age he had begun to write verses in imitation of the then much admired though now justly forgotten Eugenio Lobo; but at Salamanca he came under the influence of the purer literary taste of the elder Moratin, while to the friendship of the cultivated and well-read Cadahalso he owed his introduction to the writings of recent English poets. At the age of twenty-six Melendez obtained the prize of the Spanish Academy for the best eclogue, one of the unsuccessful competitors being the well-known Iriarte; the poem (*Batilo: egloga en alabanza de la vida del campo*, 1780) continues to be highly spoken of by native critics, who echo in various forms the remark of one of the adjudicators, that it was "redolent of the wild thyme." In 1781 Melendez went to Madrid, where Jovellanos became his friend, and obtained for him in 1783 the appointment of professor of the humanities at Salamanca. In 1784, in competition for a prize offered by the city of Madrid, he produced his longest poem, a "dramatic eclogue" entitled *Las Bodas de Camacho* ("Camacho's Wedding"), which secured the vote of the judges, but did not add to his reputation, and soon fell into neglect. His genius does not seem to have been at all dramatic; at any rate he was unfortunate in his choice of a subject so little capable of dramatic treatment as the well-known episode in *Don Quixote*. In the following year, at the age of thirty-one, he published a little volume of lyrics and pastorals which gave him the first place he still holds among Spanish poets of the 18th century. Several editions were exhausted in a single year. With poetical fame came professional advancement, and in 1789 the "Restorer of Parnassus" (*Restaurador del Parnaso*), as Melendez is sometimes pedantically called by his countrymen, received a judicial appointment at Saragossa, which in 1791 he exchanged for a chancery

<sup>1</sup> On the other hand it is not correct to appeal to the *Pœnulus* of Plautus for the epithet 'elyōn.

auditorship at Valladolid. In 1797 the publication of a new and greatly enlarged edition of his works, dedicated to the prince of the peace, was followed by his removal to Madrid to a high post in connexion with the treasury. The new poems included somewhat heavy philosophical epistles written after the manner of Young, and an unmistakably dull epic canto entitled *Caída de Luzbel* ("The Fall of Lucifer"), suggested by Milton, as well as an *Ode to Winter*, which showed how well the author had made himself acquainted with Thomson. On the fall of his friend Jovellanos in 1798 Melendez was ordered away from Madrid, first to Medina del Campo and afterwards to Zamora, and it was not till 1802 that he was permitted to settle in Salamanca. For the next six years his literary activity was but slight, being limited to the production of a short poem on "Creation" and the preparation of an unfinished translation of the *Aeneid*. After the revolution of Aranjuez (1808) Melendez accepted from King Joseph the post of councillor of state and afterwards that of minister of public instruction, a failure of patriotism which involved him in many indignities and even dangers; in 1813 he was of course compelled to quit his country, and, after sojourning successively at Alais, Nîmes, and Toulouse, he died in considerable poverty and neglect at Montpellier, on May 24, 1817. During his exile he employed himself in the preparation of a complete edition of his works, with numerous additions and corrections; this was afterwards published, along with a life of the author by Quintana, at the expense of the Government (4 vols. 8vo, Madrid, 1820; reprinted at Paris, 1832, and at Barcelona, 1838).

MELFI, a city of Italy, in the province of Potenza, 30 miles N. of Potenza, on the road and railway between that city and Foggia, is built on a small hill on the lower slopes of Monte Volture. The castle was originally erected by Robert Guiscard, but as it now stands it is mainly the work of the Doria family, who have possessed it since the time of Charles V.; and the noble cathedral which was founded in 1155 by Robert's son and successor, Roger, has had to be subjected to a modern restoration in consequence of the earthquake of 1851. In 1871 the city had 10,945 inhabitants; the commune had 9863 in 1861 and 12,657 in 1881.

Melfi is of doubtful origin, but appears to have existed at least as early as the 4th century. By the Normans it was made the capital of Apulia in 1041, and provided with fortifications. The council held by Nicholas I. in 1059, that of Urban II. in 1090, the rebellion against Roger in 1138 and the subsequent punishment, the plunder of the town by Barbarossa in 1167, the attack by Richard, count of Acerra in 1190, and the parliament of 1223, in which Frederick II. established the constitution of the kingdom of Naples, form the principal points of interest in the annals of Melfi during the more eventful period of its history. In 1348 Joanna I. of Naples bestowed the city on Niccolò Acciajuoli; but it was shortly afterwards captured, after a six months' siege, by the king of Hungary, who transferred it to Conrad the Wolf. In 1392 Goffredo Marzano was made count of Melfi; but Joanna II. granted the lordship to the Caracciolo family, and they retained it for one hundred and seven years till the time of Charles V. An obstinate resistance was offered by the city to Lautrec de Foix in 1528; and his entrance within its walls was followed by the massacre, it is said, of 18,000 of its citizens. As a bishopric Melfi is directly dependent on the Holy See.

MELITA (Μελίτη), the classical name for MALTA (*q.v.*), was also the name borne by the modern *Meleda*, one of the Dalmatian islands, situated immediately to the south of Sabbioncello and to the north of Ragusa. It is about 24 miles in length, averaging about  $1\frac{1}{2}$  in breadth, and has a good harbour. At one time it was supposed by some authors to have been the scene of the shipwreck of St Paul, but this point has now for some time been conclusively settled in favour of Malta. See Smith, *Voyage and Shipwreck of St Paul*, 1848.

MELITO, bishop of Sardes, a Christian writer of the 2d century, is mentioned by Eusebius (*H. E.*, iv. 21)

along with Hegesippus, Dionysius of Corinth, Apollinaris of Hierapolis, Irenæus, and others, his contemporaries, as a champion of orthodoxy and upholder of apostolic tradition. Of his personal history nothing is known, and of his numerous works (which are enumerated by Eusebius) only a few fragments are now extant. They included an *Apologia* addressed to Aurelius some time between 169 and 180 A.D., two books relating to the paschal controversy, and a work entitled *Ἐκλογαί* (selections from the Old Testament), which contained the well-known catalogue of "the books of the Old Covenant." The fragments have been edited with valuable notes by Routh (*Reliquiæ Sacræ*, vol. i., 1814). It seems more than doubtful whether the *Apologia* of Melito "the Philosopher," discovered in a Syriac translation by Tattam, and subsequently edited by Cureton and Renan, ought to be attributed to this writer and not rather to another of the same name.

MELLONI, MACEDONIO (1798–1854), a distinguished physicist, was born at Parma on April 11, 1798. From 1824 to 1831 he was professor at Parma, but in the latter year he was compelled to escape to France, having taken part in the revolution. In 1839 he went to Naples as director of the conservatory of arts and handicrafts. He was likewise director of the Vesuvius observatory, a post which he held until 1848. Melloni received the Rumford medal of the Royal Society in 1834. In 1835 he was elected correspondent of the Paris Academy, and in 1839 a foreign member of the Royal Society. He died from an attack of cholera on August 11, 1854.

From the Royal Society catalogue of papers we find that Melloni produced eighty-six memoirs by himself, as well as three in connexion with other physicists. These embrace a wide range of subjects, but the reputation of Melloni as a physicist rests more especially upon his discoveries in radiant heat. Men of science were, in the early part of this century, very much in the dark with regard to the nature of the invisible heat rays. Leslie and others had indeed advanced the subject by means of the differential thermometer, but such an instrument was at the best a very poor substitute for the human eye. It was necessary to invent an instrument more nearly capable of doing for the dark rays what the eye does for those of light before any great increase in our knowledge of this subject could be expected to take place. This step was taken (shortly after Seebeck's discovery of thermo-electricity) in the construction of the thermo-multiplier or combination of thermopile and galvanometer which formed the subject of a joint memoir by Nobili and Melloni in 1831. In this memoir, after describing their instrument, these physicists confirmed the experiments of Leslie and others. They tried screens of glass, sulphate of lime, mica, and ice, also of water, oil, alcohol, and nitric acid enclosed in glass, and found an instantaneous effect produced in the index of their instrument except for ice and water, the source of heat being an iron ball below redness. After finding that most substances when used as screens stopped a much larger proportion of dark heat than they did of light, Melloni set himself to discover some body that might be transparent for dark heat. In this search he was rewarded with complete success. Rock-salt was found to possess this property; and he immediately proceeded to construct prisms and lenses of rock-salt with which he proved the refraction of dark heat, that is to say, of the heat proceeding from bodies below incandescence.

Melloni was likewise very successful in studying the action upon dark heat of screens of various substances. His experiments in this and other directions are described by Baden Powell in his report to the British Association on *Radiant Heat* (1840). The rays of the lamp were thrown upon screens of various materials in such a manner that the effect transmitted from all the screens was of a certain uniform amount. This constant radiation was then intercepted by a plate of alum, and it was found that very different quantities of heat were transmitted through the alum in the different cases. Melloni concludes that the calorific rays issuing from the various diaphanous screens are, therefore, of different qualities, and possess what may be termed the diathermancy peculiar to each of the substances through which they have passed. One of his screens was made of green glass, and he found that a piece of alum transmitted only 1 per cent. of the heat which had passed through this screen. Green glass and alum form, therefore, an antagonistic combination.

These experiments suggest naturally a new analogy between dark heat and light which could not fail to strike Melloni, and accordingly we soon find him describing an experiment with the solar rays transmitted through green glass and then intercepted by other

media. They pass copiously through rock-salt, he tells us, but feebly through alum, and hence Melloni concludes that there are amongst the solar rays some which resemble those of terrestrial heat, and in general that the differences observed between solar and terrestrial heat in the transmission of rays are to be attributed merely to the mixture in different proportions of these several species of rays. An instrument like the thermo-multiplier could not of course remain a monopoly, and shortly after its completion we find Professor James Forbes making use of it to prove the polarization of heat as well as to extend our knowledge of refraction. The brilliant researches of this experimentalist were, like those of Melloni, crowned with the Rumford medal of the Royal Society. On September 2, 1839, Arago communicated to the academy of sciences a letter by Melloni, who had found that rock-salt acquires by being smoked the power of transmitting most easily heat of low temperature, or dark heat. Forbes had discovered a similar property in mica split by heat, and he now showed that rock-salt roughened and mica scratched possess similar properties to blackened rock-salt. Melloni on his part took up the subject of polarization, and decided in favour of the equal polarizability of heat from different sources, a conclusion that did not then appear to Forbes to be in conformity with his experiments. It is very instructive to notice the loyalty which held both these experimentalists to the results of their observations. While Melloni differs from Forbes with regard to polarization, he will not allow the truth of a generalization proposed by Ampère, who had endeavoured to explain on the theory of undulations the identity of light and heat,—the difference of effect being dependent solely on the different wave-lengths, those producing heat being larger than those giving rise to light. Melloni admits that many phenomena may be explained by this hypothesis, but he mentions some experiments in which he thinks that this theory will not hold. The brilliant generalizer from without has of course a different point of view from the laborious experimentalist within. They are all worthy of scientific honour—for it is by the seeming conflict, but in reality the united efforts of workers such as these that the essential element of stability in the structure of scientific knowledge is finally secured.

MELON (*Cucumis Melo*, L.), a most polymorphic species of the order *Cucurbitaceæ*, the varieties of which are grouped by Naudin under ten tribes, while several other plants of less known characters probably belong to it.<sup>1</sup> The melon is an annual herb with palmately-lobed leaves, and bears tendrils. It is monoecious, having male and female flowers on the same plant. The flowers have deeply five-lobed campanulate corollas and three stamens. Naudin observed that in some varieties (*e.g.*, of Cantaloups) fertile stamens sometimes occur in the female flowers. It is a native of south Asia “from the foot of the Himalayas to Cape Comorin,”<sup>2</sup> where it grows spontaneously, but is cultivated in the temperate and warm regions of the whole world. It is excessively variable both in diversity of foliage and habit, but much more so in the fruit, which in some varieties is no larger than an olive, while in others it rivals the ponderous fruits of the gourd (*Cucurbita maxima*, L.). The fruit may be globular, ovoid, spindle-shaped, or serpent-like, netted or smooth-skinned, ribbed or furrowed, variously coloured externally, with white, green, or orange flesh when ripe, scented or scentless, sweet or insipid, bitter or even nauseous, &c. Like the gourd, the melon undergoes strange metamorphoses by crossing its varieties, though the latter preserve their characters when alone. The offspring, however, of all crossings are fertile. As remarkable cases of sudden changes produced by artificially crossing races, M. Naudin records that in 1859 the offspring of the wild melons *m. sauvage de l'Inde* (*C. melo agrestis*) and *m. s. d'Afrique*, le petit *m. de Figari* (*C. maculatus*?) bore quite different fruits from their parents, the former being ten to twelve times their size, ovoid, white-skinned, more or less scented, and with reddish flesh; though another individual bore fruits no larger than a nut. The offspring of *m. de Figari* after being crossed bore fruits of the serpent-melon. On the

other hand, the serpent-melon was made to bear ovoid and reticulated fruit.<sup>3</sup>

With reference to the early cultivation of the melon, Naudin thinks it is probable that the culture in Asia is as ancient as that of all other alimentary vegetables. The Egyptians grew it, or at least inferior races of melon, which were either indigenous or introduced from Asia. The Romans and doubtless the Greeks were familiar with it, though some forms may have been described as cucumbers. Columella seems to refer to the serpent-melon in the phrase *ut coluber . . . ventre cubat flexo*. Pliny describes them as *pepones* (xix. 23 to xx. 6) and Columella as *melones* (xi. 2. 53); see Pickering, *Chron. Hist., of Pl.*, 229. The melon began to be extensively cultivated in France in 1629, according to Olivier de Serres. Gerard (*Herball*, 771) figured and described in 1597 several kinds of melons or pompions, but he has apparently included gourds under the same name. Pickering observes that the melon was carried by Columbus to America, and by the Portuguese to the Malayan Archipelago.

The origin of some of the chief modern races, such as “Cantaloups,” “Dudaim,” and probably the netted sorts, is due to Persia and the neighbouring Caucasian regions. The first of these was brought to Rome from Armenia in the 16th century, and supplies the chief sorts grown for the French markets; but many others are doubtless artificial productions of West Europe.

For cultivation of the melon, see art. HORTICULTURE, and also *Gard. Chron.*, May 6, 1882, p. 596; and for references to French literature on the same see Naudin, *ut supra*, p. 82.

MELOS (Att. Gr. Μῆλος), the modern Milo, one of the Sporades of the Ægean Sea, situated at the south-west corner of the archipelago, in 36° 45' N. lat. and 24° 26' E. long., 75 miles due east from the coast of Laconia. From east to west it measures about 14 miles, from north to south 8 miles, and its area is estimated at 52 square miles. The greater portion is rugged and hilly, and the culminating point, Mount Elias in the west, reaches a height of 2538 feet. Like the rest of the cluster to which it belongs, the island as a whole is of volcanic origin, with tuff, trachyte, and obsidian among its ordinary rocks. The great natural harbour, which, with a depth diminishing from 70 to 30 fathoms, strikes in from the north-west so as to cut the island into two fairly equal portions, with an isthmus not more than 1½ miles broad, is evidently the hollow of the principal crater. In one of the caves on the south coast the heat is still so great that one cannot remain within more than a few minutes, and on the eastern shore of the harbour there is a remarkable cluster of hot sulphurous springs. Sulphur is found in abundance on the top of Mount Kalamo and elsewhere. In ancient times the alum of Milo was reckoned next to that of Egypt (Pliny, xxxv. 15 [52]), and millstones, salt (from a marsh at the east end of the harbour), and gypsum are still exported. The Melian earth (γῆ Μηλιάς), employed as a pigment by ancient artists, was probably native white-lead. Orange, olive, cypress, and arbutus trees grow throughout the island, which, however, is too dry to have any profusion of vegetation. The vine, the cotton plant, and barley are the main objects of cultivation. Including the neighbouring islands of Antimilos (4 square miles), Cimolos (16 square miles), and Polinos (5½ square miles), the total population of Melos was only 5538 in 1879.

*Antimilo*, 5½ miles north-west of Milo, is a mere uninhabited mass of trachyte, and is often called *Eriomilo* or *Desert Melos*. *Cimolos*, or *Argentiera*, less than 1 mile to the north-east, was famous in antiquity for its

<sup>1</sup> For generic characters see Benth. et Hook., *Gen. Pl.*, i. 826; and for a full account of the species of *Cucumis* and of the tribes of melon, by M. Naudin, see *Ann. des Sci. Nat.*, 4 sér., tom. xi. p. 34.

<sup>2</sup> Naudin, *l.c.*, pp. 39, 76; see also *Gard. Chron.*, 1857, p. 153, and 1858, p. 130.

<sup>3</sup> See also Naudin, in *Nouv. rech. sur l. hyb. dans les veg.*, p. 118, 1861.

figs and fuller's earth (Κιμωλία γῆ), and contained a considerable city, the remains of which still cover the cliff of St Andrews. *Polinos*, *Polybos* or *Polivo*, and *Kaimeni*, or "Burned Island," the *Île Brulée* or *Isola Bruciata* of the French and Italians, lies rather more than a mile south-east of Cimolos. It was in antiquity the subject of dispute between the Melians and Cimolians. It has long been almost uninhabited.

In ancient times the city of Melos, built terrace fashion round a hill in the north-east of the main island, was a place of considerable size; "the western wall, of Cyclopean masonry, is traceable all the way down from the summit to the sea," and among the ruins are a temple in the Corinthian style and a beautiful little theatre cleared in 1836 by order of the king of Bavaria. Painted vases (the ancient Melians were great makers of this kind of ware), bronzes, gold ornaments, and similar specimens of art workmanship have been recovered from the debris; and in 1820 the "Venus of Milo," now in the Louvre, the noblest extant representation of Aphrodite, was found in the neighbourhood of the theatre. The top of the hill is now occupied by Castro, the principal village in the island. At some distance to the south-east, at the place called Tripiti (ἡ ε., τρυπητή, "the perforated"), lies a remarkable cluster of catacombs containing frescos, &c., of evidently Christian origin. Palæa Chora, about 5 miles farther south-east, is now an almost deserted village, but down to the beginning of the last century it had about 5000 inhabitants, and it continued for a time to be considered the capital of the island.

The first occupants of Melos were probably Phœnicians, but the island was Hellenized at an early date by Minyans and Dorians from Laconia. Though its inhabitants sent a contingent to the Greek fleet at Salamis, they held aloof from the Attic league, and sought to remain neutral during the Peloponnesian War. But in 416 B.C. the Athenians, having attacked the island and compelled the Melians to surrender at discretion, slew all the men capable of bearing arms, made slaves of the women and children, and introduced a body of five hundred Athenian colonists. Lysander restored the island to its old Dorian possessors, but it never recovered its former prosperity. There were many Jewish settlers in Melos in the beginning of the Christian era, and Christianity was early introduced. During the "Frankish" period the island formed part of the duchy of Naxos, except for the few years (1341-83) when it was a separate lordship under Marco Sanudo and his daughter.

See Leyscester, "The Volcanic Group of Milo, Anti-Milo, &c.," in *Jour. Roy. Geog. Soc.*, 1852; Tournetfort, *Voyage*; Leake, *Northern Greece*, vol. iii.; Prokesch von Osten, *Denkwürdigkeiten*, &c.; and Bursian, *Geog. von Griechenland*, vol. ii.

MELROSE, a village of Roxburghshire, Scotland, on the south bank of the Tweed, 37 miles by rail south-south-east of Edinburgh. Its population has steadily advanced from 966 in 1851 to 1550 in 1881. Though a burgh of barony since 1609, it is a purely agricultural village, and would be of little interest but for the ruins of its abbey, now the property of the duke of Buccleuch. It was formerly called Little Fordell, and its present name even dates from the foundation of the monastery by David II. in 1136.

There had been a Columbite monastery of Melrose at the place now known as Old Melrose, about a mile and a half to the east of the village, but this establishment, probably never of much architectural magnificence, had, according to the *Chronicle of the Picts and Scots*, been destroyed by Kenneth M'Alpin in 839, and may never have recovered from the disaster. King David's abbey, which he entrusted to a body of Cistercian monks from Rievaulx (Riual) in Yorkshire, was dedicated on Sunday 28th July 1146; it was laid in ruins by Edward II. of England in 1322; Bruce caused the work of restoration to be vigorously prosecuted, but the edifice was again burned by Richard II. in 1385. The abbey church as it now stands consequently belongs in the main to the latter half of the 14th century and the first half of the 15th, with a good many portions of a considerably later date.

Architecturally, the abbey may be described as a splendid example of the Middle Pointed style, strongly affected on the one hand by Flamboyant and Perpendicular tendencies, and on the other by the individuality of some of the builders. Cruciform in plan, it measured 214½ feet from east to west, the width of the nave being 69 feet, and across the transepts 115½. The noble edifice was damaged by the English in 1545; and since the Reformation it has been altered to suit the necessities of Presbyterian worship (1618-1810), and

plundered by builders to supply ornaments for houses. The whole building is now in ruins. The west end and a good part of the north side have disappeared; but the elevation of the south side is nearly entire, both the transepts and the east end are externally in very fair preservation, part of the central tower is standing, and the sculptured roof still covers the east end of the chancel. Of the individual features of the building, the great eastern window has been generally most admired since Sir Walter Scott celebrated the moonlit aspect of its "slender shafts of shapely stone." It has five lights; the height is 37 feet and the width 16; and the upper portion is filled in with delicate tracery of a geometrical design. Very beautiful too is the whole gable of the south transept. In the interior, on the north side of the nave, there still stand four of the original square piers, and one of them shows a Norman "cap." The choir, the west end of which is shut off by a massive rood-screen, has been largely "spoiled by rough 17th century work"; but enough remains of the decorative detail to provoke the admiration and despair of the modern artist in stone. The facade and at the same time elaborate rendering of vegetable forms, such as the Scotch "kail," is particularly striking. It was in the abbey-church of Melrose, where Alexander II. had long before been buried near the high altar, that the heart of Bruce found its final resting-place; and among the many tombs which afterwards gathered under the same roof were those of his faithful knight James Lord Douglas, Sir William the dark knight of Liddesdale, and the hero of Chevy Chase.

The ancient muniments of the abbacy have been preserved in the archives of the earl of Morton; they were published by the Bannatyne Club (2 vols., 1837, *Liber Sancte Marie de Melros*), under the editorship of Cosmo Innes. Among the many interesting documents is one of the very earliest specimens of the Scotch tongue. The *Chronica de Mailros*, preserved among the Cotton MSS., has been twice printed,—at Oxford (1684) by Fulman, and by the Bannatyne Club (1835), edited by John Stevenson. From about 1140 till its close in 1265 the chronicle may be considered original; it was put largely under contribution by later compilers.

MELTON MOWBRAY, a market-town of England, county of Leicester, is pleasantly situated in a fertile vale, at the confluence of the Wreake and Eye, 15 miles north-east of Leicester and 104 north of London by rail. The Eye is spanned by a bridge of four arches. The town consists principally of two main streets, and is substantially built of brick. The church of St Mary, a handsome cruciform structure partly in the Early English style, and adorned by a lofty and richly ornamented tower, was heightened and otherwise enlarged in the reign of Elizabeth, and has also undergone modern improvements. There are largely endowed almshouses and several other charities. Melton is the seat of a celebrated hunting district, in connexion with which there are stables in the town capable of accommodating about eight hundred horses. It is also well known for its pork pies, and has a very large trade in Stilton cheese. There are breweries and tanneries, as well as an important cattle market. Iron-works have lately been erected. The town possesses great railway facilities. The population of the urban sanitary district in 1871 was 5033, and in 1881 it was 5766.

The old name of Melton was Medeltone, and the place is of considerable antiquity. During the Civil War it was in February 1644 the scene of the defeat, with great slaughter, of the parliamentary forces by the royalists. It is the birthplace of John Henley the orator.

MELUN, capital of the department of Seine-et-Marne, France, 28 miles south-east of Paris by railway, occupies a hill on the right bank of the Seine and the level ground at its foot. It owes its rank as "chef-lieu" to its central position merely; for there are two other towns in the department, Meaux and Fontainebleau, which have a larger population. Melun is near one of the most beautiful parts of the forest of Fontainebleau. Among the rich estates in its neighbourhood the most remarkable is the magnificent chateau of Vaux-Praslin, which belonged to Fouquet, superintendant of finances under Louis XIV. The church

of Notre Dame formerly belonged to a nunnery, now occupied by a central house of detention for twelve hundred prisoners. On the apse of the church of St Aspais may be seen a modern medallion in bronze, the work of the sculptor Chapu, representing Joan of Arc as the liberator of Melun. The population in 1881 was 12,145.

Melun is a very ancient town, and has played an important part in history. As early as the time of Cæsar's Gallic wars it was taken possession of by his lieutenant Labienus, in order to attack Lutetia with greater ease by the right bank of the Seine. It was pillaged by the Normans, and afterwards became the favourite residence of the first kings of the race of Capet; Robert and Philip I. both died there. During the Hundred Years' War Melun was given up by Jeanne of Navarre to her brother, Charles the Bad, but was retaken by the dauphin Charles and Duguesclin. In 1420 it made an heroic defence against Henry V. of England and his ally the duke of Burgundy. Ten years later the people of Melun, with the help of Joan of Arc, drove out the English. It was occupied by the League in 1589, and retaken by Henry IV. in the following year. Jacques Amyot was born there in 1504.

MELVILLE, HENRY DUNDAS, VISCOUNT (1741-1811), younger son of the Right Honourable Robert Dundas, lord president of the Scottish court of session, was born at Edinburgh in 1741, and was educated at the high school and university there. Becoming member of the faculty of advocates in 1763, he soon acquired a leading position at the bar. After his appointment as lord advocate in 1775, he gradually relinquished his legal practice to devote his attention more exclusively to public business. On entering parliament in 1774, he had joined the party of Lord North, and, notwithstanding his provincial dialect and ungraceful manner, he soon distinguished himself in the debates by his clear and argumentative speeches. After holding subordinate offices under the marquis of Lansdowne and Pitt, he in 1791 entered the cabinet as home secretary. From 1794 to 1801 he was secretary at war under Pitt, who conceived for him a special friendship. In 1802 he was elevated to the peerage as Viscount Melville and Baron Dunira. Under Pitt in 1804 he again entered office as first lord of the admiralty, when he introduced numerous improvements in the details of the department. His impeachment in 1806, for the appropriation of balances of public money remaining in his hands, resulted in his acquittal, but he never again held office. He died May 27, 1811.

MELVILLE, ANDREW (1545-1622), a distinguished Scottish scholar, theologian, and religious reformer, was the youngest son of Richard Melville, proprietor of Baldov, near Montrose, at which place Andrew was born in 1545. His father fell at the battle of Pinkie, fighting in the van of the Scottish army, two years after the birth of his son; and, his wife having soon after followed him to the grave, the young orphan, then a gentle and delicate child, was tenderly cared for by his eldest brother Richard and his amiable and pious wife, whose memory the great scholar ever afterwards cherished with the warmest gratitude and affection. At a very early age Melville began to show a strong taste for learning, and his brother did every thing in his power to give him the best education the country could then afford. The rudiments of Latin he obtained at the grammar school of Montrose, after leaving which he prosecuted the study of Greek for two years under Pierre de Marsilliers, a Frenchman whom John Erskine of Dun had induced to settle at Montrose; and such was the proficiency Melville made that on going to the university of St Andrews he excited the astonishment of both students and professors by using the Greek text of Aristotle, which no one else there understood, the Latin translation being that which was alone employed in the teaching of logic. On completing his course of study, Melville left St Andrews with the character of "the best poet, philosopher, and Grecian of any young master in the land." He then,

in 1564, being nineteen years of age, set out for France to perfect his education at the university of Paris. He there applied himself especially to the study of the Oriental languages, but he had also the advantage of attending the last course of lectures delivered by Turnebus in the Greek chair, as well as those of the celebrated Ramus, whose mode of philosophizing and plan of teaching he afterwards introduced into the universities of Scotland. From Paris he proceeded to Poitiers for the purpose of studying civil law, and though only twenty-one years of age he was apparently at once made a regent in the college of St Marceon. After a residence of three years, however, the political troubles of the country compelled him to leave France, and he then went on to Geneva, where he was warmly welcomed by Theodore Beza, at whose instigation he was appointed to fill the chair of humanity in the academy of Geneva, which then happened to be vacant. In addition to his teaching, however, he also applied himself to the further prosecution of his studies in Oriental literature, and in particular acquired from Cornelius Bertram, one of his brother professors, a knowledge of Syriac. While he resided at Geneva the massacre of St Bartholomew in 1572 drove an immense number of Protestant refugees to that city, including several of the most distinguished French men of letters of the time, with whom Melville had now the opportunity of intimate intercourse. Among these were several men deeply learned in civil law and political science, and their society no doubt tended greatly both to increase Melville's knowledge of the world and to enlarge his ideas of civil and ecclesiastical liberty—acquisitions which he must have found of essential service when at a later period as a leader of the General Assembly he had to struggle against the attempts of James VI. to crush the liberties of the church of the Scottish Reformation. In 1574 Melville returned to Scotland, and almost immediately afterwards received the appointment of principal of Glasgow University, which at the time had fallen into an almost ruinous state, the college having in fact been shut up and the students dispersed. Melville, however, with the knowledge of academic methods of training which he had obtained abroad, immediately set himself with immense energy to establish a good educational system, and in a short time his fame spread through the kingdom, and students flocked in from all quarters, till the class-rooms lately empty could not contain those who came for admission. After labouring for six years in Glasgow, and having brought the seminary into a state of the most thorough efficiency, it was thought desirable that he should undertake the same duties at St Andrews. He accordingly proceeded there in 1580, and was installed as principal of the new theological college. His duties there comprehended the teaching, not only of theology, but of the Hebrew, Chaldee, Syriac, and Rabbinical languages, and the great ability of his lectures was universally acknowledged, and excited quite a new interest in the university. The sweeping reforms, however, which his new modes of teaching necessarily involved, and even some of the new doctrines which he began to introduce, such as the non-infallibility of Aristotle, soon brought him into collision with some of the other teachers in the university; and this, along with the troubles which arose from the attempts of the court to force a bastard system of Episcopacy upon the Church of Scotland, forced him to flee into England in order to escape the consequences of an absurd charge of treason which was made against him, and which seemed to threaten a prolonged imprisonment and not improbably even his life. After an absence of twenty months he returned to Scotland in November 1585, and in March 1586 resumed his lectures in St Andrews, where he continued to fulfil the duties of his office for

twenty more years. During the whole of that time, however, his more prominent work was that of contending with unwearied energy and indomitable courage against the encroachments of an unscrupulous and tyrannical Government upon the liberties of the Scottish Church. Into the details of these it is of course impossible to enter here. But that in the main he and his coadjutors were fighting for the constitutionally guaranteed rights of the church is now admitted by all candid inquirers. (See in particular *The History of England from 1603 to 1616*, by Samuel Rawson Gardiner, vol. i. chap. ix.). The chief charge against Melville is that his fervour often led him to forget the reverence due to an "anointed monarch." Of this, however, it is not very easy now to judge. Manners at that time were rougher than at present. Any thing more rude, insolent, and brutal than James's own occasional explosions it would be difficult to match, and a king so undignified could scarcely expect to be treated with dignity. Besides, what title had one who was acting in a purely arbitrary and illegal manner to receive other than the plainest dealing,—such as being reminded that though he was king over men he was only "God's silly vassal?" Melville's rudeness (if it is to be called so) was simply the outburst of just indignation from a brave, true, and upright man, zealous only for the purity of religion and regardless of consequences to himself, and it contrasts nobly with the grovelling sycophancy of most of the English bishops towards James. The close of Melville's career in Scotland was at length brought about by James in characteristic fashion. In 1606 he and seven other clergymen of the Church of Scotland were summoned to London in order "that his majesty might treat with them of such things as would tend to settle the peace of the church." The contention of the whole of these faithful men was that the only way to accomplish that purpose was a free Assembly. Melville delivered his opinion to that effect with his accustomed freedom and boldness, and, having shortly afterwards written a sarcastic Latin epigram on some of the superstitious practices he had observed in the chapel of Hampton Court, and some eavesdropper having conveyed the lines to the king, he was committed to the Tower, and detained there for the space of four years. On regaining his liberty, and being refused permission to return to his own country, he was invited to fill a professor's chair in the university of Sedan, and there he spent the last eleven years of his brave, active, noble, and useful life. He died at Sedan in 1622, at the age of seventy-seven.

MELVILLE, GEORGE JOHN WHYTE (1821–1878), has a right to be regarded as the founder of a school of fashionable novels,—the fashionable sporting novel. He was lamented on his death as the Tyrtæus of the hunting field, the laureate of fox-hunting; all his most popular and distinctive heroes and heroines, Digby Grand, Tilbury Nogo, the Honourable Crasher, Mr Sawyer, Kate Coventry, Mrs Lascelles, are or would be mighty hunters. The eldest son of Major Whyte Melville, of Mount Melville, Fifeshire, he received his school education, like so many of his heroes, at Eton, entered the army in 1839, became captain in the Coldstream Guards in 1846, and retired in 1849. His first appearance in literature was made soon after, with a translation of Horace into fluent and graceful verse, published in 1850. His first novel was *Digby Grand*, published in 1853. Although this first effort has a good deal more in it of Lytton's early high-flying style than Whyte Melville's later works, the unflagging verve and intimate knowledge with which he described sporting scenes and sporting characters at once drew attention to him as a novelist with a new vein. His power of sustaining interest in hunting and the things connected with

hunting appeared more markedly in his next novel, *Tilbury Nogo*, contributed to the *Sporting Magazine* in 1853. He showed in the adventures of Mr Nogo, what became more apparent in his later works, that he had a surer hand in humorous narrative than in pathetic description; there are many pathetic scenes in his novels, but the pathos is sometimes rather forced, intended to point a moral—rather the pathos of the preacher than the poet. The hero of *General Bounce*, his next novel in order of publication (*Fraser's Magazine*, 1854), little as one would expect it from the title, ends in a painful manner, somewhat out of keeping with the lively middle and beginning. When the Crimean War broke out, Whyte Melville took part in it as a volunteer in the Turkish contingent; but this was the only break in his literary career from the time that he began to write novels till his death in 1878. By a strange accident, he lost his life in the hunting-field, the hero of many a stiff ride meeting his fate in galloping quietly over an ordinary ploughed field.

Twenty-one novels appeared from his pen after his return from the Crimea:—*Kate Coventry*, 1856; *The Interpreter*, 1858; *Holmby House*, 1860; *Good for Nothing*, 1861; *Market Harborough*, 1861; *The Gladiators*, 1863; *Brookes of Bridlemere*, 1864; *The Queen's Maries*, 1864; *Cerise*, 1865; *Bones and I*, 1868; *The White Rose*, 1868; *M or N*, 1869; *Contraband*, 1870; *Sarchedon*, 1871; *Satanella*, 1872; *Uncle John*, 1874; *Sister Louise*, 1875; *Katerfelto*, 1875; *Rosine*, 1876; *Roy's Wife*, 1878; *Black but Comely*, 1878. Several of these novels are historical, the *Gladiators* being perhaps the most famous of them. As an historical novelist Whyte Melville cannot be put on a level with Harrison Ainsworth for painstaking accuracy and minuteness of detail; he makes his characters live and move with great vividness, but he obviously did not know at first hand the history of the periods chosen by him. It is on his portraiture of contemporary sporting society that his reputation as a novelist must rest; and, though now and then a character reappears, such as the supercilious stud-groom, the dark and wary steeple-chaser, or the fascinating sporting widow, his variety in the invention of incidents is amazing. Whyte Melville was not merely the annalist of sporting society for his generation, but may also be fairly described as the principal moralist of that society; he exerted a considerable and a wholesome influence on the manners and morals of the gilded youth of his time. His *Songs and Verses* and his metrical *Legend of the True Cross*, though respectable in point of versification, are hardly worth mentioning on their own merits.

MELVILL VAN CARNBEE, PRIETER, BARON, an eminent Dutch geographer, was born at the Hague 20th May 1816, and died October 24, 1856. He traced his descent from an old Scotch family, originally it is said of Hungarian extraction. Destined for the navy, in which his grandfather had won distinction, Melvill imbibed a taste for hydrography and cartography as a student under Pilaar in the college of Medemblik, and he showed his capacity as a surveyor on his very first voyage to the Dutch Indies (1835). In 1839 he was again in the East, and was now attached to the hydrographical bureau at Batavia. With the assistance of the long-neglected documents collected by the old company, he completed in wonderfully short time his first great hydrographical work—a map of Java in five sheets, accompanied by sailing directions (Amsterdam, 1842; 2d revised edition, 1849),—which was received with great applause. Melvill remained in India till 1845 collecting materials for his second great hydrographical work, the chart of the waters between Sumatra and Borneo (two sheets, 1845 and 1846, revised edition of first sheet 1847; compare the descriptive memoir in Tindal and

Swart's *Journal*, 1846). On his return to Holland Melvill was attached to the naval department with the special charge of studying the history of the hydrography of the Dutch Indies. He also undertook, in connexion with Von Siebold, the publication of the *Moniteur des Indes*, a valuable series of scientific papers, mainly from his own pen, on the foreign possessions of Holland, which was continued for three years. In 1850 Melvill returned to India as lieutenant of the first class and adjutant to Vice-Admiral Van den Bosch; and after the premature death of this commander he was again appointed keeper of the charts at Batavia. He was one of the founders and for a time the president of the new society for natural science (1850). In 1853 he obtained exemption from active naval service that he might devote himself to a general atlas of the Dutch Indies; and under the most unfavourable circumstances he prosecuted the task with incredible energy. But he was not to see its completion. Just after he had lost his young wife and new-born son he was called in 1856 to be director of the marine establishment of Onrust; and there he soon fell a victim to climate, dying after much suffering in the hospital of Weltevreden, only forty years of age. In spite of delays caused by the engraving of the maps in Holland, no fewer than twenty-five sheets were already finished, but it was not till 1862 that the whole plan, embracing sixty sheets, was ably brought to a close by Lieutenant-Colonel W. F. Versteeg. The premature loss of Melvill was severely felt not only in Holland but in foreign countries, where, as shown by his connexion with the geographical societies of Paris, London, Berlin, and Bergen, his labours were highly esteemed. His industry and energy were equalled only by the benevolence and warmth of his heart. In 1843 he received the decoration of the Netherlands Lion, in 1849 that of the Legion of Honour.

MEMEL, the most northerly town in Germany, and the principal seat of the Baltic timber trade, is situated in the district of Königsberg, Prussia, at the mouth of the Dange, and on the bank of a sound connecting the Kurische Haff with the Baltic Sea. On the side next the sea the town is defended by a citadel and other fortifications, and the entrance to the large and fine harbour is protected by a lighthouse. Largely rebuilt since a destructive fire in 1854, Memel contains several churches, a gymnasium, a school of navigation, an exchange, and various judicial and official establishments. It also possesses large iron-foundries, shipbuilding yards, breweries, distilleries, and manufactories of chemicals, soap, and amber wares. By far the most important interest of the town, however, is its trade, the chief items in which are timber and the grain and other agricultural products of Lithuania. The timber is brought by river from the forests of Russia, and is prepared for exportation by about thirty saw-mills. The annual value of timber exported is about £600,000. In 1880 the port of Memel was entered by 898 ships with an aggregate burden of 164,374 tons, and cleared by 932 vessels with a burden of 164,441 tons. The population of Memel in 1880 was 19,660.

Memel was founded in 1252 by Poppo von Osterna, grand master of the Teutonic order, and was at first called New Dortmund and afterwards Memmelburg. It soon acquired a considerable trade, and joined the Hanseatic League. During the 13th, 14th, and 15th centuries it was repeatedly burned down by its hostile neighbours, the Lithuanians and Poles, and in the 17th century it remained for some time in the possession of Sweden. In 1757, and again in 1813, it was occupied by Russian troops. After the battle of Jena, King Frederick William III. retired to Memel; and there, in 1807, a treaty was concluded between England and Prussia. The poet Simon Dach and the astronomer Argelander were natives of Memel.

MEMLING, HANS, a painter of the 15th century, whose art gave a passing lustre to Bruges in the period of its political and commercial decline. Though much

has been written respecting the rise and fall of the school which made this city famous, it still remains a moot question whether that school ever truly existed. Like Rome or Naples, Bruges absorbed the talents which were formed and developed in humbler centres. John Van Eyck first gained repute at Ghent and the Hague before he acquired a domicile elsewhere, and Memling, we have reason to think, was a skilled artist before he settled at Bruges. Yet if the question should be asked where the manner of Memling was shaped, and where he acquired the skill which he displayed at Bruges, we shall be greatly at a loss to reply. The annals of the city are silent as to the birth and education of a painter whose name was inaccurately spelt by different authors, and whose identity was lost under the various appellations of Hans and Hausse, or Hemling and Memling. But no other city of the Netherlands has vindicated the right which Bruges had no means of proving. Travellers who came to Bruges were only told that Memling's masterpieces were preserved in the hospital of St John. In one of these pictures it was said a portrait of the artist might be discovered; on the sculptured ornaments of a porch enframing one of its subjects an incident of the master's life might be traced,—his danger as he lay senseless in the street, his rescue as charitable people carried his body to the hospital. The legend grew too. It came to be told how the great artist began life as a soldier who went to the wars under Charles the Bold, and came back riddled with wounds from the field of Nancy. Wandering homeward in a disabled state in 1477, he fainted in the streets of Bruges, and was cured by the Hospitallers. Unknown to them, and a stranger to Bruges, he gave tangible proofs of his skill to the brethren of St John, and showed his gratitude by refusing payment for a picture he had painted. Unhappily the legend refutes itself. The portrait of Memling is a myth; the carvings of the capitals of the porch represent the ordinary incidents attending the reception of patients at an hospital. Memling did indeed paint for the Hospitallers, but he painted not one but many pictures, and he did so in 1479 and 1480, being probably known to his patrons of St John by many masterpieces even before the battle of Nancy.

Memling is only connected with military operations in a mediate and distant sense. His name appears on a list of subscribers to the loan which was raised by Maximilian of Austria to push hostilities against France in the year 1480. When he signed this list his position was that of a resident at Bruges who had probably lived there long enough to acquire a large practice and its advantages in the form of lands and tenements. In 1477, when he is said to have fallen, and when Charles the Bold was killed, he was under contract to furnish an altarpiece for the guild chapel of the booksellers of Bruges; and this altarpiece, now preserved, under the name of the Seven Griefs of Mary, in the gallery of Turin, is one of the fine creations of his riper age, and not inferior in any way to those of 1479 in the hospital of St John, which for their part are hardly less interesting as illustrative of the master's power than the Last Judgment in the cathedral of Dantzic. Critical opinion has been unanimous in assigning the altarpiece of Dantzic to Memling, and by this it affirms that Memling was a resident and a skilled artist at Bruges in 1473; for there is no doubt that the Last Judgment was painted and sold to a merchant at Bruges, who shipped it there on board of a vessel bound to the Mediterranean, which was captured by a Dantzic privateer in that very year. But, in order that Memling's repute should be so fair as to make his pictures purchasable, as this had been, by an agent of the Medici at Bruges, it is incumbent on us to acknowledge that he had furnished sufficient proofs before that time of the skill which excited the wonder of such highly cultivated

patrons; and thus we come to admit without much difficulty the possible truth of a report made by a chronicler of the 16th century that Memling had sittings from Isabella, consort of Philip the Good of Burgundy, in the year 1450.

It is characteristic that the very oldest allusions to pictures connected with Memling's name are those which point to relations with the Burgundian court. The inventories of Margaret of Austria, drawn up in 1524, allude to a triptych of the God of Pity by Roger van der Weyden, of which the wings containing angels were by "Master Hans." But this entry is less important as affording testimony in favour of the preservation of Memling's work than as showing his connexion with an older Flemish craftsman. For ages Roger van der Weyden was acknowledged as an artist of the school of Bruges, until records of undisputed authenticity demonstrated that he was bred at Tournai and settled at Brussels. Nothing seems more natural than the conjunction of his name with that of Memling as the author of an altarpiece, since, though Memling's youth remains obscure, it is clear from the style of his manhood that he was taught in the painting-room of Van der Weyden. Nor is it beyond the limits of probability that it was Van der Weyden who received commissions at a distance from Brussels, and first took his pupil to Bruges, where he afterwards dwelt. The clearest evidence of the connexion of the two masters is that afforded by pictures, and particularly an altarpiece, which has alternately been assigned to each of them, and which may possibly be due to the joint labours of both. In this altarpiece, which is a triptych ordered for a patron of the house of Sforza, we find the style of Van der Weyden in the central panel of the Crucifixion, and that of Memling in the episodes on the wings. Yet the whole piece was assigned to the former in the Zambeccari collection at Bologna, whilst it was attributed to the latter at the Middleton sale in London in 1872. At first, we may think, a closer resemblance might be traced between the two artists than that disclosed in later works of Memling, but the delicate organization of the younger painter, perhaps also a milder appreciation of the duties of a Christian artist, may have led Memling to realize a sweet and perfect ideal, without losing, on that account, the feeling of his master. He certainly exchanged the asceticism of Van der Weyden for a sentiment of less energetic concentration. He softened his teacher's asperities and bitter hardness of expression.

In the very oldest form in which Memling's style is displayed, or rather in that example which represents the Baptist in the gallery of Munich, we are supposed to contemplate an effort of the year 1470. The finish of this piece is scarcely surpassed, though the subject is more important, by that of the Last Judgment of Dantzic. But the latter is more interesting than the former because it tells how Memling, long after Roger's death and his own settlement at Bruges, preserved the traditions of sacred art which had been applied in the first part of the century by Roger van der Weyden to the Last Judgment of Beaune. All that Memling did was to purge his master's manner of excessive stringency, and add to his other qualities a velvet softness of pigment, a delicate transparency of colours and yielding grace of slender forms. That such a beautiful work as the Last Judgment of Dantzic should have been bought for the Italian market is not surprising when we recollect that picture-fanciers in that country were familiar with the beauties of Memling's compositions as shown in the preference given to them by such purchasers as Cardinal Grimani and Cardinal Bembo at Venice, and the heads of the house of Medici at Florence. But Memling's reputation was not confined to Italy or Flanders. The Madonna and Saints which so lately passed out of the Duchatel collection into the gallery of the Louvre, the Virgin and Child of Sir John Donne at Chiswick, and other noblespecimens in English and Continental private houses show that his work was as widely known and appreciated as it could be in the state of civilization of the 16th century. It was perhaps not their sole attraction that they gave the most tender and delicate possible impersonations of the "Mother of Christ" that could suit the taste of that age in any European country. But the portraits of the donors with which they were mostly combined were more characteristic, and probably more remarkable as likenesses than any that Memling's contemporaries could produce. Nor is it

unreasonable to think that his success as a portrait painter, which is manifested in isolated busts as well as in altarpieces, was of a kind to react with effect on the Venetian school, which undoubtedly was affected by the partiality of Antonello da Messina for trans-Alpine types studied in Flanders in Memling's time. The portraits of Sir John Donne and his wife and children in the Chiswick altarpiece are not less remarkable as models of drawing and finish than as refined presentations of persons of distinction; nor is any difference in this respect to be found in the splendid groups of father, mother, and children which fill the noble altarpiece of the Louvre. As single portraits, the busts of Burgomaster Moreel and his wife in the museum of Brussels, and their daughter the Sibyl Zambetha in the hospital of Bruges, are the finest and most interesting of specimens. The Seven Griefs of Mary in the gallery of Turin, to which we may add the Seven Joys of Mary in the Pinakothek of Munich, are illustrations of the habit which clung to the art of Flanders, of representing a cycle of subjects on the different planes of a single picture, where a wide expanse of ground is covered with incidents from the Passion in the form common to the action of sacred plays. The time came, no doubt, when the players took their cue from the painters, as in the Ghent procession, which was formed on the model of Van Eyck's Adoration of the Lamb. But in Memling's days there were still some original "players," and the public was not averse to seeing illustrations of their work. In the first period of the development of Belgian art too, when the Flemings assigned more importance to carved work than to painting, and yet refused to accept sculpture without colour, it was natural that the sculptor should multiply incidents on bas-reliefs which were coated with tinting in the semblance of nature. Memling's pictures imitate reliefs so far as they abound in variety of episodes, and are marked by absence of contrast in light and shade or want of toning by gradations of atmosphere. Yet with all these peculiarities his works are very pleasant to the eye, because they are always graceful and quiet.

The masterpiece of Memling's later years, a shrine containing relics of St Ursula in the hospital of Bruges, is fairly supposed to have been ordered and finished in 1480 after the painter had become acquainted with the scenery of the Rhine. This shrine is one of the most interesting monuments of mediæval art in Flanders, not only because it is beautifully executed, but because it reveals some part of the life of the painter who produced it, and illustrates the picturesque legend of Ursula and her comrades. The delicacy of finish in its miniature figures, the variety of its landscapes and costume, the marvellous patience with which its details are given, are all matters of enjoyment to the spectator. There is later work of the master in the St Christopher and Saints of 1484 in the academy, or the Newenhoven Madonna in the hospital of Bruges, or a large Crucifixion with scenes from the Passion, of 1491, in the cathedral of Lübeck. But as we near the close of Memling's career we observe that his practice has become larger than he can compass alone; and, as usual in such cases, the labour of disciples is substituted for his own. The registers of the painters' corporation at Bruges give the names of two apprentices who served their time with Memling and paid dues on admission to the guild in 1480 and 1486. These subordinates remained obscure.

It would be easy to form a long list of pictures by Memling in the galleries of Berlin, Florence, London, Madrid, Paris, Rome, and Vienna, and pieces equally remarkable in many private collections of England and the Continent. These have all been described, and are widely known. The present notice must be closed with the admission that pictures tell more of Memling's life than records. The date of the master's death is not better certified than that of his birth. This much, however, is certain. The trustees of Memling's will appeared before the court of wards at Bruges on the 10th of December 1495, and we gather from records of that date and place that Memling died a short time before, leaving behind several children and a considerable property. (J. A. C.)

MEMML. See MARTINI, SIMONE.

MEMMINGEN, a town of Bavaria, in the district of Schwaben and Neuburg, is situated about 35 miles to the south-west of Augsburg, near the river Iller. It is a well-built town, still partly surrounded with walls, and contains a Roman Catholic and three Protestant churches, a town-house of 1580, and several schools and charitable institutions. Its industrial products are yarn, calico, woollen goods, and thread. A considerable trade is carried on in hops, which are extensively cultivated in the neighbourhood, and in wool, leather, and grain. The population in 1880 was 8050.

Memmingen, first mentioned in a document of 1010, belonged originally to the Guelph family. In 1286 it became a free city of the empire, a position which it maintained down to 1802, when it was allotted to Bavaria. In 1529 Memmingen was one of the "pro-

testing" towns represented at the diet of Spire. During the Thirty Years' War it was alternately occupied by Swedes and Imperialists. In 1800 the French under Moreau gained a victory over the Austrians near Memmingen. Compare Dobel, *Memmingen im Reformationszeitalter*, 1877-78.

**MEMNON.** In the Homeric mythology (or rather the mythology of the *Troica* in the much fuller form in which it existed in the times of Pindar and the tragic poets) this hero was called the son of Tithonus (the half-brother of Priam) and Eos (Aurora). Tradition represented him as an Ethiopian prince who came to assist the Trojans against the Greeks, and performed prodigies of valour, but was at length killed by Achilles, after having himself slain Antilochus, the son of Nestor, an event alluded to in Pindar, *Pyth.*, vi. 32-39. His story must have been very famous, for more than one Greek play was composed bearing the title.

The chief source from which our knowledge about Memnon as a chief is derived is the second book of the *Post-Homerica*, by Quintus Smyrnaeus, where his exploits and death are described at length. That Memnon was slain by Achilles is more than once affirmed by Pindar (*Nem.*, vi. 52; *Isthm.*, iv. 41, vii. 54). He is mentioned also in the *Odyssey* (xi. 522), with especial praise for personal beauty; but the allusion to him is quite casual, and is one of many proofs that the compilation of that and the sister epic presupposes in the reader or hearer a full knowledge of the whole tale of Troy. Modern philology associates Memnon—like Achilles, whom he so closely resembles in many particulars, and like Sarpedon, who seems the representative of Memnon in the *Iliad*—with solar phenomena. He was the son of the dawn, and, though he might vanish from sight for a time, he could not be destroyed, and therefore it was said that Zeus, moved by the tears of his mother, granted him immortality. In this respect, as also in wearing bright armour made by Hephaestus, he is the counterpart of Achilles, who symbolizes the mid-day sun in his glory; and that Memnon is said to have come from the far east, i.e., from the region of sunrise, is in itself significant. Ovid, in a beautiful elegy on the death of Tibullus, *Amor.*, lib. iii. 9, 3, thus associates the fates of Memnon and Achilles:—

Memnona si mater, mater ploravit Achillem,  
Et tangunt magnas tristia fata deas,  
Flebilis indignos, Elegeia, solve capillos;  
Ah nimis ex vero nunc tibi nomen erit.

Like the body of the dead hero Sarpedon (*Il.*, xvi. 681), so that of Memnon was borne through the air, a legend represented on Greek vases of a rather early date. This appears to mean that the sun, the offspring of the dawn, careers through the sky to the place of his departure in the west. Another account represents Zeus as having sent forth birds from the funeral-pile of Memnon, which straightway fought with each other, and many fell back as victims to the soul of the hero.

The mere fact that a *Memnonium*, or temple in honour of the hero, was erected both at Susa and at Egyptian Thebes, both of which places were centres of sun-worship, is a strong confirmation of the probability, derived from his mythical pedigree, that he was really a sun-god. Sir G. W. Cox remarks,<sup>1</sup> "of Memnon's head the story was told that it retained the prophetic power of the living Helios or of Surya. The story is found in the myth of the Teutonic Wismir, and it might have been related of Kephalos, the head of the sun;" and again (p. 267), "Eos, the mother of Memnon, is so transparently the morning that her child must rise again as surely as the sun reappears to run his daily course across the heaven."

With respect to the meaning of the name, it may possibly be the same as Agamemnon, which has a prefix

meaning *brave*.<sup>2</sup> It has been thought that *Μέμνων* and *μνήμων*, "mindful," are but forms of the same word, and that the prophetic power attributed to the head of the Egyptian Memnon, which was said to utter sounds at sunrise, is connected with this idea. It was said that the sound resembled the moaning noise or the sharp twang of a harp-string, and it may even be surmised that the syllables *mem-non* imitated the resonance. The Egyptian head is said to be a bust of King Amenophis;<sup>3</sup> but if the Greeks fancied it uttered the word *memnon*, they would have called it by that name. The tendency, however, to give a Greek shape and inflexion to words which sounded barbarous will sufficiently account for the misnaming of the statue.

Strabo, lib. xvii. p. 816, declares that he himself heard it in company with Ælius Gallus and several of his friends, and Pausanias (i. 42, 2) says "one would compare the sound most nearly to the broken chord of a harp or a lute." See also Juv., *Sat.*, xv. 5; Tac., *Ann.*, ii. 61.

Memnon, as an Ethiopian, was of course represented as a black; hence Virgil (*Æn.*, i. 493) speaks of "*nigri Memnonis arma*." The figure itself was cut out of black basalt, but that is a material not uncommon in Egypt. Speaking quite generally, it seems reasonable to conclude that the Memnon from Ethiopia (which the early Greeks placed in the far east rather than in the south) typifies the eastern sun summoned to oppose the enemies of darkness from the west.

**MEMPHIS**, the capital of the old Egyptian empire, founded by Menes, the first historical king; see vol. vii. pp. 731, 770. In the time of Strabo (xvii. p. 807) it was the second city of Egypt, inferior only to Alexandria, and with a mixed population like the latter. Memphis was still an important though declining place at the time of the Moslem conquest. Its final fall was due to the rise of the Arabic city of Fostat on the right bank of the Nile almost opposite the northern end of the old capital; and its ruins, so far as they still lay above ground, gradually disappeared, being used as a quarry for the new city. The remains of "Menf" were still imposing late in the 12th century, when they were described by 'Abd el-Latif. In the Old Testament Memphis is mentioned under the names of Moph (Hos. ix. 6) and Noph (Isa. xix. 13; Jer. ii. 16; Ezek. xxx. 13, 16).

**MEMPHIS**, a city of the United States, and port of entry, capital of Shelby county, Tennessee, is situated on the east bank of the Mississippi river just below the mouth of Wolf river, in about 35° 8' N. lat. and 90° 5' W. long., 450 miles below St Louis and 826 miles above New Orleans. The bluff on which the city stands has an average elevation of 47½ feet above high-water mark, with a further fall of 36 feet to extreme low water. Memphis is methodically and tastefully planned, and is adorned with many elegant private residences and public buildings, conspicuous among the latter being the United States custom house, located upon the esplanade between Front Street and the river, and built of the best quality of marble, the product of Tennessee quarries. A small park in the centre of the city contains a bust of Andrew Jackson. The streets are mostly well-paved, and are supplied with water from the Wolf river by the Holly system. The bayou Gayoso, with several branches, intersects the city, and prior to 1880 received most of its drainage. Since that date over 40 miles of sewers and more than that length of subsoil drain-tiles have been constructed on the Waring system, providing the city with a superior system of drainage.

<sup>1</sup> Sir G. W. Cox, *Mythology of the Aryans*, p. 268, ed. 2.

<sup>2</sup> *Φαμένωφ*, as the Thebans themselves said, according to Pausanias, cited below.

<sup>1</sup> *Mythology and Folklore*, p. 134.

Memphis is the largest city of the State, and the most important commercial city on the Mississippi between St Louis and New Orleans. The largest sea-going vessels ascend the river to this point, and navigation is open at all seasons of the year. The city also possesses abundant facilities for transportation by railway in every direction. Memphis ranks as the largest interior cotton-market in the United States. The receipts for the season ending September 1, 1881, were 470,267 bales, with a value of \$23,090,109. The aggregate receipts from the mercantile and manufacturing interests for the year ending September 1, 1882, amounted to about \$60,000,000, of which the trade in groceries and western products contributed nearly \$40,000,000; dry goods, clothing, boots and shoes, and general merchandise \$15,000,000; and various home manufactures about \$5,000,000. There are oil-mills and refineries, whose annual product of about 30,000 barrels of cotton-seed oil, together with oil-cake and re-ginned cotton, amounts to over \$1,000,000. There are also numerous foundries, machine shops, flouring-mills, and manufactories of carriages, furniture, and tobacco.

The city contains, besides the usual religious, educational and commercial institutions, a public library of 9000 volumes, three daily and ten weekly newspapers, a chamber of commerce, and a cotton exchange.

Memphis was laid out as a village in 1820, and incorporated as a city in 1831. Its population at each census since has been as follows:—3360 in 1840, 8841 in 1850, 22,623 in 1860, 40,226 in 1870, and 33,592 in 1880.

According to a census taken on October 1, 1882, the population within the city limits was 47,976 (29,130 white and 18,846 coloured).

During the civil war Memphis was early occupied by the Union forces (June 6, 1862) after a naval engagement in which Commodore Davis with a fleet of nine gunboats and rams defeated a similar Confederate fleet of eight vessels, and captured or destroyed all of them but one. The city was held by Federal troops to the close of the war, with the exception of a brief occupation, in August 1864, by General Forrest, who captured several hundred prisoners, but immediately withdrew. The decrease of population between 1870 and 1880 was due to the ravages of yellow fever in 1873, 1878, and 1879. The epidemic of 1873 resulted in over two thousand deaths. In 1878, according to the report of the Howard Relief Association, the number of those attacked with the fever was 15,000, and the number of deaths reached the total of 5150, of whom 4250 were whites and 900 coloured. At the return of the fever in 1879 better care and strict quarantine arrangements prevailed, but there were 1595 cases, with 497 deaths. During the epidemics of 1878 and 1879 fully two-thirds of the population fled from the city, many of whom died of the fever at other places, and a still larger number did not return. For three months during each year business was wholly suspended, and all ingress or egress except for the most necessary purposes was forbidden. The prostration of the business of the place left the city almost hopelessly bankrupt, and as a means of relief the legislature of the State in January 1879 repealed the city's charter, and, assuming exclusive control of its taxation and finances, constituted it simply a "taxing district," placing its government in the hands of a "legislative council." This anomalous proceeding has been declared constitutional by the supreme court of Tennessee. Under it Memphis is at least regaining its prosperity, and by thoroughly cleansing, repaving, and sewerage its streets, and supervising the construction of buildings, is likely to become one of the healthiest cities on the Mississippi river.
